Acronyms	xvi
1 Introduction and Literature Review	1
1.1 Cancer Research in the Post-Genomic Era	1
1.1.1 Cancer is a Global Health Issue	2
1.1.1.1 The Genetics and Molecular Biology of Cancers	3
1.1.2 The Genomics Revolution in Cancer Research	3
1.1.2.1 High-Throughput Technologies	4
1.1.2.2 Bioinformatics and Genomic Data	5
1.1.3 Genomics Projects	5
1.1.3.1 The Cancer Genome Project	6
1.1.3.2 The Cancer Genome Atlas Project	6
1.1.4 Genomic Cancer Medicine	8
1.1.4.1 Cancer Genes and Driver Mutations	8
1.1.4.2 Precision Cancer Medicine	9
1.1.4.3 Molecular Diagnostics and Pan-Cancer Medicine	9
1.1.4.4 Targeted Therapeutics and Pharmacogenomics	10
1.1.5 Systems and Network Biology	11
1.2 Synthetic Lethal Cancer Medicine	12
1.2.1 Synthetic Lethal Genetic Interactions	12
1.2.2 Synthetic Lethal Concepts in Genetics	14
1.2.3 Synthetic Lethality in Model Systems	14
1.2.3.1 Synthetic Lethal Pathways and Networks	15
1.2.3.2 Evolution of Synthetic Lethality	15
1.2.4 Synthetic Lethality in Cancer	16
1.2.5 Clinical Impact of Synthetic Lethality in Cancer	18
1.2.6 High-throughput Screening for Synthetic Lethality	19
1.2.6.1 Synthetic Lethal Screens	21
1.2.7 Computational Prediction of Synthetic Lethality	22
1.2.7.1 Bioinformatics Approaches to Genetic Interactions	22
1.2.7.2 Comparative Genomics	24
1.2.7.3 Analysis and Modelling of Protein Data	26
1.2.7.4 Differential Gene Expression	28
1.2.7.5 Data Mining and Machine Learning	29

1.2.7.6	Mutual Exclusivity and Bimodality	31
1.2.7.7	Rationale for Further Development	33
1.3	E-cadherin as a Synthetic Lethal Target	33
1.3.1	The <i>CDH1</i> gene and its Biological Functions	33
1.3.1.1	Cytoskeleton	34
1.3.1.2	Extracellular and Tumour Micro-environment	34
1.3.1.3	Cell-Cell Adhesion and Signalling	34
1.3.2	<i>CDH1</i> as a Tumour (and Invasion) Suppressor	35
1.3.2.1	Breast Cancers and Invasion	35
1.3.3	Hereditary Diffuse Gastric (and Lobular Breast) Cancer	35
1.3.4	Cell Line Models of <i>CDH1</i> Null Mutations	37
1.4	Summary and Research Direction of Thesis	37
1.4.1	Thesis Aims	39
2	Methods and Resources	40
2.1	Bioinformatics Resources for Genomics Research	40
2.1.1	Public Data and Software Packages	40
2.1.1.1	Cancer Genome Atlas Data	41
2.1.1.2	Reactome and Annotation Data	42
2.2	Data Handling	42
2.2.1	Normalisation	42
2.2.2	Sample Triage	42
2.2.3	Metagenes and the Singular Value Decomposition	43
2.2.4	Candidate Triage and Integration with Screen Data	45
2.3	Techniques	46
2.3.1	Statistical Procedures and Tests	46
2.3.2	Gene Set Over-representation Analysis	47
2.3.3	Clustering	47
2.3.4	Heatmap	47
2.3.5	Modelling and Simulations	48
2.3.5.1	Receiver Operating Characteristic Curves	49
2.3.6	Resampling Analysis	49
2.4	Pathway Structure Methods	50
2.4.1	Network and Graph Analysis	50
2.4.2	Sourcing Graph Structure Data	51
2.4.3	Constructing Pathway Subgraphs	51
2.4.4	Network Analysis Metrics	52
2.5	Implementation	53
2.5.1	Computational Resources and Linux Utilities	53
2.5.2	R Language and Packages	54
2.5.3	High Performance and Parallel Computing	57
3	Methods Developed During Thesis	59
3.1	A Synthetic Lethal Detection Methodology	59
3.2	Synthetic Lethal Simulation and Modelling	61
3.2.1	A Model of Synthetic Lethality in Expression Data	62

3.2.2	Simulation Procedure	66
3.3	Detecting Simulated Synthetic Lethal Partners	69
3.3.1	Binomial Simulation of Synthetic Lethality	69
3.3.2	Multivariate Normal Simulation of Synthetic Lethality	71
3.3.2.1	Multivariate Normal Simulation with Correlated Genes	73
3.3.2.2	Specificity with Query-Correlated Pathways	81
3.4	Graph Structure Methods	83
3.4.1	Upstream and Downstream Gene Detection	83
3.4.1.1	Permutation Analysis for Statistical Significance	84
3.4.2	Simulating Gene Expression from Graph Structures	85
3.5	Customised Functions and Packages Developed	89
3.5.1	Synthetic Lethal Interaction Prediction Tool	89
3.5.2	Data Visualisation	90
3.5.3	Extensions to the iGraph Package	91
3.5.3.1	Sampling Simulated Data from Graph Structures	91
3.5.3.2	Plotting Directed Graph Structures	91
3.5.3.3	Computing Information Centrality	93
3.5.3.4	Testing Pathway Structure with Permutation Testing	93
3.5.3.5	Metapackage to Install iGraph Functions	94
4	Synthetic Lethal Analysis of Gene Expression Data	95
4.1	Synthetic Lethal Genes in Breast Cancer	96
4.1.1	Synthetic Lethal Pathways in Breast Cancer	97
4.1.2	Expression Profiles of Synthetic Lethal Partners	99
4.1.2.1	Subgroup Pathway Analysis	102
4.2	Comparing Synthetic Lethal Gene Candidates	104
4.2.1	Primary siRNA Screen Candidates	104
4.2.2	Comparison with Correlation	104
4.2.3	Comparison with Primary Screen Viability	107
4.2.4	Comparison with Secondary siRNA Screen Validation	109
4.2.5	Comparison to Primary Screen at Pathway Level	110
4.2.5.1	Resampling Genes for Pathway Enrichment	112
4.2.6	Integrating Synthetic Lethal Pathways and Screens	117
4.3	Synthetic Lethal Pathway Metagenes	118
4.4	Replication in Stomach Cancer	120
4.5	Discussion	121
4.5.1	Strengths of the SLIPT Methodology	121
4.5.2	Synthetic Lethal Pathways for E-cadherin	122
4.5.3	Replication and Validation	124
4.5.3.1	Integration with siRNA Screening	124
4.5.3.2	Replication across Tissues	125
4.6	Summary	125

5	Synthetic Lethal Pathway Structure	127
5.1	Synthetic Lethal Genes in Reactome Pathways	127
5.1.1	The PI3K/AKT Pathway	128
5.1.2	The Extracellular Matrix	130
5.1.3	G Protein Coupled Receptors	133
5.1.4	Gene Regulation and Translation	133
5.2	Network Analysis of Synthetic Lethal Genes	135
5.2.1	Gene Connectivity and Vertex Degree	136
5.2.2	Gene Importance and Centrality	137
	5.2.2.1 Information Centrality	137
	5.2.2.2 PageRank Centrality	139
5.3	Relationships between Synthetic Lethal Genes	140
5.3.1	Detecting Upstream or Downstream Synthetic Lethality	141
5.3.2	Resampling for Synthetic Lethal Pathway Structure	143
5.4	Discussion	145
5.5	Summary	147
6	Simulation and Modelling of Synthetic Lethal Pathways	149
6.1	Synthetic Lethal Detection Methods	150
6.1.1	Performance of SLIPT and χ^2 across Quantiles	150
	6.1.1.1 Correlated Query Genes affects Specificity	154
6.1.2	Alternative Synthetic Lethal Detection Strategies	156
	6.1.2.1 Correlation for Synthetic Lethal Detection	156
	6.1.2.2 Testing for Bimodality with BiSEp	158
6.2	Simulations with Graph Structures	159
6.2.1	Performance over Graph Structures	160
	6.2.1.1 Simple Graph Structures	160
	6.2.1.2 Constructed Graph Structures	162
6.2.2	Performance with Inhibitions	165
6.2.3	Synthetic Lethality across Graph Structures	170
6.2.4	Performance within a Large Simulated Datasets	173
6.3	Simulations in More Complex Graph Structures	178
6.3.1	Simulations over Pathway-based Graphs	179
6.3.2	Pathway Structures in a Large Simulated Datasets	181
6.4	Discussion	184
	6.4.1 Simulation Procedure	184
	6.4.2 Comparing Methods with Simulated Data	185
	6.4.3 Design and Performance of SLIPT	186
	6.4.4 Simulations from Graph Structures	188
6.5	Summary	189
7	Discussion	191
7.1	Synthetic Lethality and <i>CDH1</i> Biology	191
	7.1.1 Established Functions of <i>CDH1</i>	192
	7.1.2 The Molecular Role of <i>CDH1</i> in Cancer	192
7.2	Significance	193

7.2.1	Synthetic Lethality in the Genomic Era	193
7.2.2	Clinical Interventions based on Synthetic Lethality	195
7.3	Future Directions	196
7.4	Conclusions	198
	Bibliography	200
A	Sample Quality	226
A.1	Sample Correlation	226
A.2	Replicate Samples in TCGA Breast Cancer Data	229
B	Software Used for Thesis	233
C	Mutation Analysis in Breast Cancer	242
C.1	Synthetic Lethal Genes and Pathways	242
C.2	Synthetic Lethal Expression Profiles	243
C.3	Comparison to Primary Screen	246
C.3.1	Resampling Analysis	248
C.4	Compare SLIPT genes	250
D	Metagene Analysis	252
D.1	Pathway Signature Expression	252
D.2	Synthetic Lethal Reactome Metagenes	256
E	Intrinsic Subtyping	257
F	Stomach Expression Analysis	259
F.1	Synthetic Lethal Genes and Pathways	259
F.2	Comparison to Primary Screen	263
F.2.1	Resampling Analysis	265
F.3	Metagene Analysis	267
G	Synthetic Lethal Genes in Pathways	268
H	Network Analysis for Mutation SLIPT	275
I	Pathway Structure for Mutation SLIPT	278
J	Performance of SLIPT and χ^2	280
J.1	Correlated Query Genes affects Specificity	286
K	Simulations on Graph Structures	292
K.0.1	Simulations from Inhibiting Graph Structures	293
K.1	Simulation across Graph Structures	296
K.2	Simulations from Complex Graph Structures	300
K.2.1	Simulations from Complex Inhibiting Graphs	303
K.3	Simulations from Pathway Graph Structures	309

List of Figures

1.1	Synthetic genetic interactions	13
1.2	Synthetic lethality in cancer	17
2.1	Read count density	44
2.2	Read count sample mean	44
3.1	Framework for synthetic lethal prediction	60
3.2	Synthetic lethal prediction adapted for mutation	61
3.3	A model of synthetic lethal gene expression	63
3.4	Modelling synthetic lethal gene expression	64
3.5	Synthetic lethality with multiple genes	65
3.6	Simulating gene function	67
3.7	Simulating synthetic lethal gene function	67
3.8	Simulating synthetic lethal gene expression	68
3.9	Performance of binomial simulations	70
3.10	Comparison of statistical performance	70
3.11	Performance of multivariate normal simulations	72
3.12	Simulating expression with correlated gene blocks	74
3.13	Simulating expression with correlated gene blocks	75
3.14	Synthetic lethal prediction across simulations	77
3.15	Performance with correlations	78
3.16	Comparison of statistical performance with correlation structure	79
3.17	Performance with query correlations	80
3.18	Statistical evaluation of directional criteria	81
3.19	Performance of directional criteria	82
3.20	Simulated graph structures	86
3.21	Simulating expression from a graph structure	87
3.22	Simulating expression from graph structure with inhibitions	88
3.23	Demonstration of violin plots with custom features	92
3.24	Demonstration of annotated heatmap	92
3.25	Simulating graph structures	93
4.1	Synthetic lethal expression profiles of analysed samples	100
4.2	Comparison of SLIPT with siRNA	105
4.3	Comparison of SLIPT and siRNA genes with correlation	105
4.4	Comparison of SLIPT and siRNA genes with correlation	107
4.5	Comparison of SLIPT and siRNA genes with screen viability	108

4.6	Comparison of SLIPT genes with siRNA screen viability	108
4.7	Resampled intersection of SLIPT and siRNA candidate genes	113
5.1	Synthetic lethality in the PI3K cascade	129
5.2	Synthetic lethality in Elastic Fibre Formation	131
5.3	Synthetic lethality in Fibrin Clot Formation	132
5.4	Synthetic lethality in the GPCRs	134
5.5	Synthetic lethality and vertex degree	136
5.6	Synthetic lethality and centrality	138
5.7	Synthetic lethality and PageRank	140
5.8	Structure of synthetic lethality resampling	142
6.1	Performance of χ^2 and SLIPT across quantiles	152
6.2	Performance of χ^2 and SLIPT across quantiles with more genes	153
6.3	Performance of χ^2 and SLIPT across quantiles with query correlation	154
6.4	Performance of χ^2 and SLIPT across quantiles with query correlation and more genes	155
6.5	Performance of negative correlation and SLIPT	157
6.6	Simple graph structures	160
6.7	Performance of simulations on a simple graph	161
6.8	Performance of simulations is similar in simple graphs	163
6.9	Performance of simulations on a pathway	164
6.10	Performance of simulations on a simple graph with inhibition	166
6.11	Performance is higher on a simple inhibiting graph	167
6.12	Performance of simulations on a constructed graph with inhibition	168
6.13	Performance is affected by inhibition in graphs	170
6.14	Detection of synthetic lethality within a graph structure	172
6.15	Performance of simulations including a simple graph	175
6.16	Performance on a simple graph improves with more genes	176
6.17	Performance on an inhibiting graph improves with more genes	177
6.18	Performance of simulations on the PI3K cascade	180
6.19	Performance of simulations including the PI3K cascade	182
6.20	Performance on pathways improves with more genes	183
A.1	Correlation profiles of removed samples	227
A.2	Correlation analysis and sample removal	228
A.3	Replicate excluded samples	229
A.4	Replicate samples with all remaining	230
A.5	Replicate samples with some excluded	231
C.1	Synthetic lethal expression profiles of analysed samples	244
C.2	Comparison of mtSLIPT to short interfering RNA (siRNA)	246
C.3	Compare mtSLIPT and siRNA genes with correlation	250
C.4	Compare mtSLIPT and siRNA genes with correlation	250
C.5	Compare mtSLIPT and siRNA genes with siRNA viability	251
D.1	Pathway metagene expression profiles	254

D.2	Expression profiles for estrogen receptor related genes	255
F.1	Synthetic lethal expression profiles of stomach samples	261
F.2	Comparison of SLIPT in stomach to siRNA	263
G.1	Synthetic lethality in the PI3K/AKT pathway	268
G.2	Synthetic lethality in the PI3K/AKT pathway in cancer	269
G.3	Synthetic lethality in the Extracellular Matrix	270
G.4	Synthetic lethality in the GPCR Downstream	271
G.5	Synthetic lethality in the Translation Elongation	272
G.6	Synthetic lethality in the Nonsense-mediated Decay	273
G.7	Synthetic lethality in the 3' UTR	274
H.1	Synthetic lethality and vertex degree	275
H.2	Synthetic lethality and centrality	276
H.3	Synthetic lethality and PageRank	276
I.1	Structure of synthetic lethality resampling	278
J.1	Performance of χ^2 and SLIPT across quantiles	280
J.2	Performance of χ^2 and SLIPT across quantiles	282
J.3	Performance of χ^2 and SLIPT across quantiles with more genes	284
J.4	Performance of χ^2 and SLIPT across quantiles with query correlation	286
J.5	Performance of χ^2 and SLIPT across quantiles with query correlation	288
J.6	Performance of χ^2 and SLIPT across quantiles with query correlation and more genes	290
K.1	Performance of simulations on a simple graph	292
K.2	Performance of simulations on an inhibiting graph	293
K.3	Performance of simulations on a constructed graph with inhibition	294
K.4	Performance of simulations on a constructed graph with inhibition	295
K.5	Detection of synthetic lethality within a graph structure	296
K.6	Detection of synthetic lethality within an inhibiting graph	298
K.7	Detection of synthetic lethality within an inhibiting graph	299
K.8	Performance of simulations on a branching graph	300
K.9	Performance of simulations on a complex graph	301
K.10	Performance of simulations on a large graph	302
K.11	Performance of simulations on a branching graph with inhibition	303
K.12	Performance of simulations on a branching graph with inhibition	304
K.13	Performance of simulations on a complex graph with inhibition	305
K.14	Performance of simulations on a complex graph with inhibition	306
K.15	Performance of simulations on a large constructed graph with inhibition	307
K.16	Performance of simulations on a large constructed graph with inhibition	308
K.17	Performance of simulations on the $G_{\alpha i}$ signalling pathway	309
K.18	Performance of simulations including the $G_{\alpha i}$ signalling pathway	310

List of Tables

1.1	Methods for predicting genetic interactions	23
1.2	Methods for predicting synthetic lethality in cancer	23
1.3	Methods used by Wu <i>et al.</i> (2014)	25
2.1	Excluded samples by batch and clinical characteristics.	43
2.2	Computers used during thesis	53
2.3	Linux utilities and applications used during thesis	54
2.4	R installations used during thesis	55
2.5	R Packages used during thesis	55
2.6	R packages developed during thesis	57
4.1	Candidate synthetic lethal gene partners of <i>CDH1</i> from SLIPT	97
4.2	Pathways for <i>CDH1</i> partners from SLIPT	98
4.3	Pathways for clusters of <i>CDH1</i> partners from SLIPT	103
4.4	ANOVA for synthetic lethality and correlation with <i>CDH1</i>	106
4.5	Comparison of Synthetic Lethal Interaction Prediction Tool (SLIPT) genes against secondary siRNA screen	110
4.6	Pathways for <i>CDH1</i> partners from SLIPT and siRNA	111
4.7	Pathways for <i>CDH1</i> partners from SLIPT	114
4.8	Pathways for <i>CDH1</i> partners from SLIPT and siRNA primary screen .	115
4.9	Examples of candidate metagenes synthetic lethal for <i>CDH1</i> from SLIPT	119
5.1	ANOVA for synthetic lethality and vertex degree	137
5.2	ANOVA for synthetic lethality and information centrality	138
5.3	ANOVA for synthetic lethality and PageRank centrality	139
5.4	Resampling for pathway structure of synthetic lethal detection methods	144
B.1	Complete list of R packages used during this thesis	233
C.1	Candidate synthetic lethal gene partners of <i>CDH1</i> from mtSLIPT . . .	242
C.2	Pathways for <i>CDH1</i> partners from mtSLIPT	243
C.3	Pathways for clusters of <i>CDH1</i> partners from mtSLIPT	245
C.4	Pathways for <i>CDH1</i> partners from mtSLIPT and siRNA	247
C.5	Pathways for <i>CDH1</i> partners from mtSLIPT	248
C.6	Pathways for <i>CDH1</i> partners from mtSLIPT and siRNA primary screen	249
D.1	Candidate synthetic lethal metagenes against <i>CDH1</i> from mtSLIPT . .	256

E.1	Comparison of intrinsic subtypes	257
F.1	Synthetic lethal gene partners of <i>CDH1</i> from SLIPT in stomach cancer	259
F.2	Pathways for <i>CDH1</i> partners from SLIPT in stomach cancer	260
F.3	Pathways for clusters of <i>CDH1</i> partners in stomach SLIPT	262
F.4	Pathways for <i>CDH1</i> partners from SLIPT and siRNA	264
F.5	Pathways for <i>CDH1</i> partners from SLIPT in stomach cancer	265
F.6	Pathways for <i>CDH1</i> partners from SLIPT in stomach and siRNA	266
F.7	Synthetic lethal metagenes against <i>CDH1</i> in stomach cancer	267
H.1	ANOVA for synthetic lethality and vertex degree	277
H.2	ANOVA for synthetic lethality and information centrality	277
H.3	ANOVA for synthetic lethality and PageRank centrality	277
I.1	Resampling for pathway structure of synthetic lethal detection methods	279

Glossary

allele	A gene variant with a specific sequence and phenotype.
bioinformatics	Statistical or computational approaches to biological data or research tools.
cancer	A class of diseases, formally “malignant neoplasm”, of abnormal cellular growth and spread to other organs.
cancer gene	A gene which is involved in the malignancy of some cancers, encompassing oncogenes and tumour suppressors , which have molecular aberrations in cancer or variants which predispose individuals to cancer.
chemoprevention	The use of drugs to prevent early-stage cancers, generally applied to high-risk mutation carriers.
chemotherapy	The use of cytotoxic drugs to treat cancers, in combinations, generally applied to advanced stage cancers.
compound screen	A high-throughput screen performed using a library of chemical compounds.
computational biology	Applying computational or mathematical modelling to understanding biological systems and relationships.
driver mutation	A mutation which promotes cancer growth.
E-cadherin	Epithelial cadherin (calcium-dependent adhesion), a cell-adhesion protein encoded by <i>CDH1</i> .
edge or link	A relationship connecting a pair of elements of a graph structure or network, may be weighted or directional.

epistasis (biological)	The effects of a gene modifying or masking the phenotype of another gene.
epistasis (statistical)	A divergence of the observed double mutant phenotype from that expected based on the respective phenotypes of single mutant (Fisher, 1919).
essential	A gene which is required to be functional or expressed for a cell or organism to be viable, grow or develop.
familial	A trait recurrently occurring in families, not necessarily with a genetic cause.
functional redundancy	Genes which perform a common function, also known as genetic redundancy.
gene expression	A measure of the relative expression of each gene from the mRNA extracted from (pooled) cells.
genetic robustness	A system of biological pathways which (has evolved to) continue to function as a whole under various conditions, including the inactivation of various individual genes.
genome	All of the DNA sequence in the genome.
genomic	The use of data from all genes in the genome.
germline mutation	A mutation that occurred in germline cells and is passed between generation.
graph or network	A mathematical structure modelling or depicting the relationships between elements.
hereditary	A trait or disease which has a genetic cause and is inherited from family members.
high-throughput screen	An experimental procedure to perform a large scale series of chemical, genetic, or pharmacological tests.
hub	A central or highly connected component of a network.
induced essentiality	A gene becoming essential to viability under certain conditions, including inactivation of a synthetic lethal partner.

intrinsic subtype	Distinguishing cancer by molecular and genetic features.
metagene	A consistent signal of expression for a collection of genes such as a biological pathway, derived from singular value decomposition.
microarray	A high-throughput technique to measure presence or abundance of nucleic acid sequences from binding to probes.
molecular profile	A combination of genetic and biochemical measures which identifies characteristic traits of a tumour.
molecular subtype	A classification of cancers based on an identification using molecular properties.
mutant	A variant or dysfunctional phenotype arising from a mutation in a gene.
mutation	A change in DNA sequence that disrupts gene function.
non-oncogene addiction	The dependence of a cancer cell on functioning non-mutant genes.
'omics	A combination of approaches to generating biological data with high-throughput procedures such as genomics, proteomics or metabolomics.
oncogene	A gene that potentially causes cancer, typically by over-expression or mutant gene variants.
oncogene addiction	The dependence of a cancer cell on a specific oncogenic pathway.
pan cancer	A focus on the molecular and genetic features across cancers in different tissues.
passenger mutation	A mutation that occurs in cancers but does not affect the growth of cancers.
pathway	A series of biomolecules that produces a particular product or biological function.
pleiotropy	When a gene has multiple biological functions.
precision medicine	The application of prevention and treatment measures to target diseases by molecular and genetic features.

recurrent mutation	The repeated occurrence of mutations in a particular gene across cancers.
RNAi screen	A high-throughput screen performed using a RNA interference (RNAi).
RNA-Seq	The generation of transcriptome data from sequencing RNA.
scale-free	A property of a network which has a power law vertex degree distribution, that is several highly connected hub genes and many with very few connections.
shortest path	A path with the fewest possible edges which connects two particular vertices .
small world	A property of a network which is highly connected and has a low characteristic path length, derived from the mean shortest path length across all pairs of nodes.
somatic mutation	A mutation that occurs in somatic cells, during a patient's lifespan.
sporadic cancer	Cancers which do occur in patients with a family history or carry a high-risk genetic variant.
synthetic dosage lethal	A synthetic genetic interaction (SGI) analogous to synthetic lethality where where one gene is inactivated and the other over-expressed.
synthetic lethal	Genetic interactions where inactivation of multiple genes is inviable (or deleterious) which are viable if inactivated separately.
synthetic lethal screen	A high-throughput screen performed on isogenic cell lines to detect genes for which inhibition specifically deleterious to the null mutant genotype.
synthetic rescue	A synthetic genetic interaction when the combined mutations restores the wild-type the phenotype of one of the mutations .
synthetic sick	Genetic interactions where inactivation of multiple genes is deleterious which are viable if inactivated separately.

synthetic suppression	A synthetic genetic interaction when the combined mutations (partially) suppresses the mutant phenotype of one of the mutations .
targeted therapy	Cancer treatment that specifically acts against a molecular target, in contrast to standard chemotherapy.
transcriptome	All of the genes expressed in the genome.
treatment	Medical procedures for a disease to improve patient outcomes.
tumour	An abnormal lump of tissue or growth of cells, may be cancerous.
tumour suppressor	A gene potentially causes cancer, typically by disruption of functions which protect the cell from cancer.
vertex degree	A network metric of connectivity of vertices which uses the number of edges connected to each vertex or node .
vertex or node	An element of a graph structure or network.
wild-type	A natural phenotype of a trait or the normally functional allele which encodes it.

Acronyms

ADP	Adenosine Diphosphate.
ANOVA	Analysis of Variance.
AUROC	Area Under the Receiver Operating Characteristic (curve).
BiSEp	Bimodal Subsetting Expression.
CCLE	Cancer Cell Line Encyclopaedia.
cDNA	Complementary DNA (from mRNA).
CGP	Cancer Genome Project.
CNV	Copy Number Variation.
COSMIC	Catalogue Of Somatic Mutations In Cancer.
CpG	5'-C-phosphate-G-3'.
DAISY	Data Mining Synthetic Lethal Identification Pipeline.
DNA	Deoxyribonucleic Acid.
EMT	Epithelial-Mesenchymal Transition.
FDR	False Discovery Rate.
GO	Gene Ontology.
GPCR	G Protein Coupled Receptor.
HDAC	Histone Deacetylase.
HDGC	Hereditary Diffuse Gastric Cancer.
HLRCC	Hereditary Leiomyomatosis and Renal Cell Carcinoma.
JAK	Janus Kinase.
microRNA	Micro RNA.
mRNA	Messenger RNA.
MSI	Microsatellite Instability.

mtSLIPT	Synthetic Lethal Interaction Prediction Tool (against mutation).
NGS	Next-Generation Sequencing.
PARP	Poly- ADP -Ribose Polymerase.
PCR	Polymerase Chain Reaction.
PI3K	Phosphoinositide 3-kinase.
PPI	Protein-Protein Interaction.
RNA	Ribonucleic Acid.
RNAi	RNA Interference.
ROC	Reciever Operating Characteristic (curve).
RSEM	RNA-Seq by Expectation Maximization (normalisation).
SGA	Synthetic Gene Array (technique).
SGI	Synthetic Genetic Interaction.
shRNA	Short Hairpin RNA.
siRNA	Short Interfering RNA.
SL	Synthetic Lethal.
SLIPT	Synthetic Lethal Interaction Prediction Tool.
SNP	Single Nucleotide Polymorphism.
SR	Synthetic Rescue (or viability).
SS	Synthetic Suppression.

Chapter 1

Introduction and Literature Review

This thesis presents research into genetic interactions using [genomics](#) data and [bioinformatics](#) approaches. Chapter 1 introduces recent developments in [genomics](#) and [bioinformatics](#), particularly in their application to [cancer](#) research. Studies of [synthetic lethal](#) interactions, which have fundamental importance in genetics in model organisms and renewed relevance in [cancer](#) biology specifically, will be discussed and reviewed in detail. A bioinformatic approach to [synthetic lethal](#) interactions enables a wider exploration of the function of genes and proteins in [cancer](#) cells, in contrast with candidate gene and experimental screening approaches. [Synthetic lethal](#) drug design aims to develop [treatments](#) to specificity against loss of function [mutations](#) in [tumour suppressor](#) genes, such as *CDH1* (which encodes [E-cadherin](#)) and was the focus of the analysis in this thesis. The role of *CDH1* in cellular and [cancer](#) biology is therefore also briefly reviewed.

1.1 Cancer Research in the Post-Genomic Era

[Genomic](#) technologies are expected to significantly impact on the clinical treatment of [cancers](#) along with wider applications of genetics ([Goodwin *et al.*, 2016](#); [Roychowdhury and Chinnaiyan, 2016](#)). These technologies enable focused genetics investigations on candidate genes selected from [bioinformatics](#) analysis of [genomics](#) data. Facilitated by rapidly developing technologies, large-scale projects have investigated populations ([1000 Genomes, 2010](#)), [cancers](#) ([Dickson, 1999](#); [Zhang *et al.*, 2011](#)), and functional [genomics](#) ([Kawai *et al.*, 2001](#); [ENCODE, 2004](#)), however, [genomic](#) technologies have yet to be widely adopted in healthcare or oncology ([Roychowdhury and Chinnaiyan, 2016](#); [Waldron, 2016](#)). [bioinformatics](#) analysis for interpretation of [genomic](#) data is one of the main approaches to address this disparity ([Goodwin *et al.*, 2016](#)). Here, I outline

the [cancer genomics](#) projects and findings which have led to availability of [genomics](#) data used in this thesis, and recent findings in [cancer](#) research which demonstrate potential applications of using this data.

1.1.1 Cancer is a Global Health Issue

Cancers are diseases of malignant cellular growth which typically involve [tumour](#) formation, invasion of tissues and spread to other organs. Cancers are the second leading cause of death globally ([WHO, 2017](#)), with an estimated annual incidence of 14.1 million cases and annual mortality of 8.2 million people ([Ferlay *et al.*, 2015](#)). Breast and stomach [cancers](#) are among the most prevalent [cancers](#). Breast cancer is the most common [cancer](#) in women and has an estimated annual incidence of 1.6 million cases and mortality of 520,000 people. Stomach cancer has an estimated annual incidence of 950,000 cases and a mortality of 723,000 people. Cancer is also a major health concern here in New Zealand, with 19,100 people (including 2500 cases of breast cancer and 370 cases of stomach cancer) diagnosed annually ([Hanna, 2003](#)), near the highest incidence (age-standardised per capita) of [cancer](#) in the world ([Ferlay *et al.*, 2015](#)).

While environmental factors often play a role, genetics is an important contributor to cancer risk. Most [cancers](#) occur more frequently with age and family history. Cancers arise from dysregulated cellular growth or differentiation. These can occur through genetic [mutations](#) or alterations in gene regulation or [expression](#) which generally accumulate as the disease develops. Therefore, early diagnosis is important to ensure patient survival and quality of life. Identification of patients with genetic variants or family histories at a high-risk of particular cancers is an important health issue. These high-risk individuals are regularly monitored for some cancers and are sometimes offered preventative surgery or treatment for pre-cancerous tissue ([Guilford *et al.*, 2010](#); [Scheuer *et al.*, 2002](#)).

[Chemotherapy](#) is a treatment for many advanced stage cancers, designed to inhibit rapidly growing cells. However, this approach often has severe adverse effects, a narrow therapeutic window, and is not suitable for [chemopreventative](#) application in many cases ([Kaelin, Jr, 2009](#)). Patients at high-risk of cancers are offered surveillance and preventative surgery but these approaches are not completely effective at preventing cancers and may impact on quality of life ([Guilford *et al.*, 2010](#)). Alternative [chemoprevention](#) and treatment strategies based on molecular biology and other fields are being investigated, including targeted molecular therapeutics ([Bozovic-Spasojevic *et al.*, 2012](#)).

1.1.1.1 The Genetics and Molecular Biology of Cancers

Cancers involve dysregulation of genes including [mutations](#) which occur during a patient’s lifetime and [hereditary mutations](#) which predispose them to high-risk cancers ([American Cancer Society, 2017](#); [Guilford *et al.*, 1998](#); [NCI, 2015](#)). Due to these [familial](#) cancer syndromes, [hereditary](#) risk factors, and the molecular changes occurring in them, [cancers](#) are in part a genetic disease involving many [cancer genes](#) ([Stratton *et al.*, 2009](#); [Vogelstein *et al.*, 2013](#)). The occurrence of [somatic mutation mutations](#) increases the risk of [cancer](#) with age. An association of cancer incidence with the stem cell divisions in which [mutations](#) could occur across tissue types, suggests that cancers may be inseparably coupled with aging ([Tomasetti and Vogelstein, 2015](#)).

[Hanahan and Weinberg \(2000\)](#) proposed the “hallmarks of cancer”, molecular and cellular traits shared across cancers. These form the basis of a rational approach to categorising the complex changes that occur in [cancer](#). These traits include limitless replication potential, signals for indefinite growth, and invasive or metastatic capabilities. [Cancers](#) also evade apoptosis and the immune system, and sustain angiogenesis and energy metabolism ([Hanahan and Weinberg, 2011](#)). To achieve this, [cancer](#) cells change their [genomes](#) and the [tumour](#) microenvironment. [Genomic](#) instability has a role in the survival and proliferation of [cancer](#) cells and the progression of disease, as these malignant characteristics are acquired. Identifying the genetic mechanisms involved in the acquisition of these traits is important for understanding and effectively inhibiting [cancer](#).

1.1.2 The Genomics Revolution in Cancer Research

[Genomic](#) technologies have transformed genetics research, including the study of health and disease ([Goodwin *et al.*, 2016](#); [Lander, 2011](#)). [Genomics](#) enables systematic, unbiased studies across all of the genes in the [genomes](#). Cancer [genomics](#) investigations have been widely applied to different tissues across [molecular profiles](#) ([Bamford *et al.*, 2004](#); [Weinstein *et al.*, 2013](#); [Zhang *et al.*, 2011](#)). [Genomes](#) sequencing technologies continue to improve and become feasible in a wider range of applications.

[Genomics](#) has been used in many investigations ([Goodwin *et al.*, 2016](#)) but relatively few of the potential applications in healthcare have been realised yet ([Roychowdhury and Chinnaian, 2016](#); [Tran *et al.*, 2012](#)). Cancer [genomics](#), in particular, could have numerous benefits across diagnostics, prognosis, management, and treatment ([Roychowdhury and Chinnaian, 2016](#)). While direct impact of [genomics](#) on the clinic has

been limited thus far, the [cancer genes](#) and therapeutic targets identified have begun to be introduced in the clinic ([Stratton *et al.*, 2009](#)).

1.1.2.1 High-Throughput Technologies

These investigations have been enabled by recent developments in [genomics](#) technologies, including [microarrays](#) and more recently “Next-Generation Sequencing” (NGS), which can both be used to generate high-throughput [expression](#) data. [Microarray](#) are a high-throughput molecular technique, reducing the cost, time, and labour required to study genes at the “genome” scale ([Schena, 1996](#)). [Microarray](#) can detect genotype or [expression](#) across many genes, making it feasible to perform on a statistically informative number of samples. [Microarray](#) are manufactured with probes which measure binding of nucleotides which either detect the presence of a sequence such as a [single nucleotide polymorphism \(SNP\)](#) or quantify sequences for [DNA](#) copy number, [gene expression](#), or [DNA CpG dinucleotide \(CpG\)](#) methylation. In addition to being more versatile, with higher-throughput than [polymerase chain reaction \(PCR\)](#) based techniques, [microarrays](#) are considered cost-effective, particularly when scaled up to a large number of probes.

The introduction of massively parallel sequencing technologies has further expanded high-throughput molecular studies and the availability of [genomics](#) data. NGS enables rapid *de novo* [genomes](#) and [transcriptome](#) sequencing, in addition to [gene expression](#) studies ([Goodwin *et al.*, 2016](#)). However, the cost of sequencing for [gene expression](#) studies is still considerably higher than a [microarray](#) study, limiting feasible sample sizes, and NGS studies have large compute requirements to handle the raw data. In many cases, the benefits of NGS technologies outweigh the additional cost. NGS technologies have the advantage of greater potential accuracy and sensitivity than [microarrays](#). NGS has a wider dynamic range than [microarrays](#) and are not limited to genes with an already characterised sequence or functions ([Tarazona *et al.*, 2011](#)).

NGS is highly adaptable to different applications, including [DNA](#) sequencing (obtaining the base sequence for the exome or whole [genome](#)) or RNA-Seq ([Goodwin *et al.*, 2016](#); [Tran *et al.*, 2012](#); [Waldron, 2016](#)). RNA-Seq of the [transcriptome](#) is a common adaptation where [RNA](#) is reverse transcribed and sequenced from the resulting [complementary DNA \(cDNA\)](#). This is utilised to quantify the levels of [RNA](#) and identify which regions of [DNA](#) are expressed. Subsets of the nucleic acid may be extracted for sequencing such as the coding regions of [DNA](#) (for the “exome”), mRNA, or [micro RNA \(microRNA\)](#). These “omics” technologies ([Roychowdhury and Chinnaiyan,](#)

2016; Waldron, 2016) are applicable across a wide range of biomolecules to generate “molecular profiles” of a cell or sample (Perou *et al.*, 2000).

NGS technologies continue to be refined (Goodwin *et al.*, 2016) with Illumina (the platform used to generate data in this project) and competitors continuing to improve products and decrease costs. As such, RNA-Seq for examining transcriptomes or expression studies is a growing field and will continue to be generated for a range of samples. The technology may yet improve (Goodwin *et al.*, 2016) with developments in speed and accuracy (such as semi-conductor platforms) or long reads, single molecule sequences (such as Pacific Biosciences, Oxford Nanopore, and Quantum Biosystems Japan). Due to the benefits of sequencing and the availability of public data, this thesis has focused on gene expression data generated by RNA-Seq. RNA-Seq data is publicly available from large-scale cancer genomics projects and the methods analysis developed for RNA-Seq data could be applied to future genomics technologies.

1.1.2.2 Bioinformatics and Genomic Data

Genomic technologies have generated data at a scale which requires computational, mathematical, and statistical expertise to handle this data effectively (Markowitz, 2017; Tran *et al.*, 2012), in addition to an understanding of the biological context and research questions. The interdisciplinary field of “bioinformatics”, which draws upon these skills, focuses specifically on making inferences from genomics data or developing the tools to do so. Gene expression analysis is the focus of many bioinformatics research groups, drawing upon statistical approaches to appropriately handle microarray and RNA-Seq data along with making biological inferences from a large number of statistical tests.

Bioinformatics is often confused with the broader field “computational biology” (Markowitz, 2017), which focuses on modelling and simulating aspects of biology and is not necessarily limited to genetics or data analysis. In practice, many researchers identify with both bioinformatics and computational biology or use techniques in both fields. This thesis uses many of these approaches, mainly in bioinformatics, to address biological research questions pertaining to synthetic lethal interactions.

1.1.3 Genomics Projects

Genomic projects have also been applied to various organisms, functional genetics (Kawai *et al.*, 2001; ENCODE, 2004), and human populations focusing on variability between individuals and health or disease risk (HapMap, 2003; 1000 Genomes, 2010). International projects and consortiums have begun to release data gathered using com-

mon agreed upon protocols across laboratories. These include many [genomics](#) projects including cancer [genomics](#) projects discussed below. The quality, consistency, and accessibility of these international projects is appealing, particularly for [gene expression](#) datasets where the more recent, larger projects have switched from [microarray](#) to [RNA-Seq](#) technologies.

1.1.3.1 The Cancer Genome Project

The [Cancer Genome Project \(CGP\)](#) was among the first [genomics](#) investigations into cancer ([Dickson, 1999](#)), using the human [genomes](#) sequence ([Collins and Barker, 2007](#); [Lander *et al.*, 2001](#)), the cancer research literature, and sequencing the genes of cancers themselves. The main aim of the Cancer [Genomes](#) Project was to discover “[cancer genes](#)”, which are frequently mutated in cancers by comparing cancer and normal tissue samples. These include both “[oncogenes](#)” (which drive cancer growth) and “[tumour suppressors](#)” (which protect against cancers) that are functionally activated and inactivated in cancers respectively. This project is ongoing and the continues to maintain the [Catalogue Of Somatic Mutations In Cancer \(COSMIC\)](#), a database of [cancer genes](#) ([COSMIC, 2016](#)). It includes 1,257,487 samples with 4,175,8787 gene [mutations](#) curated from 23,870 publications, including 29,112 whole [genomes](#) ([COSMIC, 2016](#)).

1.1.3.2 The Cancer Genome Atlas Project

The [Cancer Genome Atlas \(TCGA\)](#) network initially set out to demonstrate utility in a pilot project on brain ([McLendon *et al.*, 2008](#)), ovarian ([Bell *et al.*, 2011](#)), and squamous cell lung ([Hammerman *et al.*, 2012](#)) cancers. The project then expanded, aiming to analyse 500 samples each for 20-25 [tumour](#) tissue types. [TCGA](#) has since exceeded that goal, with data available for 33 cancer types including 10 “rare” cancers, a total of over 10,000 samples ([TCGA, 2017](#)). The [TCGA](#) projects set out to generate a molecular “[profile](#)” of the [tumour](#) (and some matched normal tissue) samples: genotype, [somatic mutations](#), [gene expression](#), [microRNA](#), [DNA](#) copy number, [DNA](#) methylation, and protein levels. Data which cannot be used to identify the patients is are publicly available

The [Cancer Genome Atlas](#) pilot projects ([Bell *et al.*, 2011](#); [Hammerman *et al.*, 2012](#); [McLendon *et al.*, 2008](#)) serve to demonstrate the power of applying [genomic](#) technologies to cancer research at such as scale. [TCGA](#) demonstrated the potential discovery of the molecular basis of cancer with these tissues, including the describing recurrently mutated genes in each cancer, identifying differentially methylated regions, and proposing transcriptional subtypes for ovarian cancers. The molecular aberrations

in each cancer represent potential therapeutic targets in some cases and some were shown to have an impact on patient survival.

The TCGA breast cancer analysis (Koboldt *et al.*, 2012) consisted of 802 samples with exomes, copy number variants, RPPA protein quantification, and DNA methylation, mRNA, and microRNA arrays, with 97 whole genomes sequenced. Four main molecular classes were identified to subtype the samples, despite considerable heterogeneity between samples. Recurrent mutations across more than 10% of samples were identified in the *TP53*, *PIK3CA*, and *GATA3* genes. In a further analysis of 817 breast cancer samples including 127 invasive lobular breast and 88 mixed type samples (Ciriello *et al.*, 2015), 3 molecular subtypes of lobular breast cancer were identified. Lobular breast cancer was also characterised by recurrent mutations in the *CDH1*, *PTEN*, *TBX2*, and *FOXA1* genes.

TCGA stomach cancer analysis of 295 samples (Bass *et al.*, 2014) identified molecular subtypes of stomach cancers characterised by: the Epstein-Barr virus, microsatellite instability (MSI), genomic instability, and chromosomal instability. Aberrations in *PD-L1*, *PIK3CA*, and *JAK2* were also identified in stomach cancers which may present therapeutic targets.

TCGA has identified various genes as recurrent, driver mutations across cancer types which are likely to have a role in driving the development of these cancers and present a molecular target that could be applied across tissue types. In addition to disregarding the tissue-based distinction between colon and rectal cancers based on molecular similarity (Muzny *et al.*, 2012), TCGA has observed differences within tumour types and proposed molecular subtyping for breast, clear cell renal, papillary renal, stomach, skin, bladder, and prostate cancers (Abeshouse *et al.*, 2015; Akbani *et al.*, 2015; Bass *et al.*, 2014; Ciriello *et al.*, 2015; Creighton *et al.*, 2013; Hammerman *et al.*, 2012; Koboldt *et al.*, 2012; Linehan *et al.*, 2016; Muzny *et al.*, 2012; Weinstein *et al.*, 2014).

The “Pan Cancer” TCGA project (Hoadley *et al.*, 2014; Weinstein *et al.*, 2013) analysed 3527 samples across 12 tissue types. This project performed a comprehensive analysis of molecular data across cancer types to identify molecular similarities and differences. These included recurrent *TP53*, *BRCA1* and *BRCA2* mutations, HER2 over-expression, and MSI across cancer types. The Pan Cancer project has identified 11 molecular subtypes across these tissues, with only 5 of these corresponding to tissue cancer types due to molecular similarities shared across cancer types (Hoadley *et al.*, 2014). The project further supports the genomic stratification of cancer patients,

demonstrated in breast cancer (Parker *et al.*, 2009; Pereira *et al.*, 2016; Perou *et al.*, 2000), and there being core molecular characteristics across cancers (Hanahan and Weinberg, 2000, 2011).

While these findings contribute to further understanding cancer biology within and across tissue types, the main objective of such projects is to publicly release data to analyse in future investigations (McLendon *et al.*, 2008; TCGA, 2017; Weinstein *et al.*, 2013). These serve as a vast resource of common and rare cancer types and are publicly available for further analysis (cBioPortal, 2017; TCGA, 2017; Zhang *et al.*, 2011).

1.1.4 Genomic Cancer Medicine

Cancer **genomics** has substantial potential for impacts in cancer medicine: from diagnosis to treatment (Roychowdhury and Chinnaiyan, 2016; Tran *et al.*, 2012). Beyond direct use of **genomes** or **RNA-Seq** in clinical laboratories, **genomic** studies also generate biomarkers and inform development of **treatments**. These are likely to have a more immediate patient benefit considering the cost of routine **genomes** sequencing for diagnostics.

1.1.4.1 Cancer Genes and Driver Mutations

There are two main classes of “**cancer genes**” (Futreal *et al.*, 2001). Oncogenes are activated in cancers either by gain of function **mutations** in proto-oncogenes, amplification of **DNA**, or elevated **gene expression**. Their normal functions are typically to regulate stem cells or to promote cellular growth, with **recurrent mutations** that are typically concentrated to particular gene regions (“hotspots”). Conversely, **tumour suppressor genes** are those inactivated in cancer either by loss of function **mutations**, deletion of **DNA** copies, or reduced of **gene expression**, including hypermethylation. Their normal functions are typically to regulate cell division, **DNA** repair, and cell signalling. Detecting these **cancer genes** has accelerated with **genomic** technologies, as demonstrated by COSMIC and TCGA (COSMIC, 2016; Weinstein *et al.*, 2013). Recurrent **mutations**, **DNA** copy number variants, differential **gene expression**, or differential **DNA** methylation are all indicative of **cancer genes** (Mattison *et al.*, 2009), which can be detected in **genomics** data (Pereira *et al.*, 2016; Weinstein *et al.*, 2013).

Distinguishing important “**driver**” **mutations** in **cancer genes** from “**passenger mutation**” **mutations** is challenging due to patient variation, tumour heterogeneity, and genomic instability producing many variant gene sequences (Stratton *et al.*, 2009; Tran *et al.*, 2012). Driver **mutations** can be identified by whether they co-occur or are mutually exclusive with **mutations** in other genes in cancers, are **recurrently mutated**

across a significant proportion of samples for a specific tissue type, or if [mutations](#) are recurrent across different cancer tissue types ([cBioPortal, 2017](#); [Pereira *et al.*, 2016](#); [COSMIC, 2016](#); [Weinstein *et al.*, 2013](#); [Zhang *et al.*, 2011](#)). Approximately 140 [driver mutations](#) have been identified, including many novel genes in particular cancers from [genomic](#) studies, with 2–8 in typically occurring in each tumour usually affecting cell fate, survival, or [genomes](#) maintenance ([Vogelstein *et al.*, 2013](#)). There remains a need to translate the identification of many [cancer genes](#) and [driver mutations](#) to patient benefit by repurposing or designing of [therapeutic interventions](#) against these molecular targets.

1.1.4.2 Precision Cancer Medicine

The importance of genomics is emphasised in translational cancer research in contrast with current strategies of healthcare based on what works well for the most of the population. Cancers could eventually be treated by their genomic features ([Roychowdhury and Chinnaiyan, 2016](#)), particularly grouping patients by the [mutation](#), [expression](#), or [DNA](#) methylation profiles of their cancers, which is already done in part ([Parker *et al.*, 2009](#)). Identifying actionable molecular targets is a key aspect of “[precision medicine](#)”, the rationale to target [molecular subtypes](#) with separate treatment strategies ([Glaire *et al.*, 2017](#)). To this end many [driver mutations](#) and [gene expression](#) signatures for distinguishing cancers have been identified. Some oncogenic [driver mutations](#) have effective pharmacological inhibitors designed against them but there remain many [cancer genes](#) and [mutations](#), particularly [tumour suppressors](#), for which there is not yet a [targeted therapy](#).

1.1.4.3 Molecular Diagnostics and Pan-Cancer Medicine

Molecular features such as [mutations](#) or [gene expression](#) signatures have been proposed to diagnose tumour subtypes. In breast cancer, several distinct “[intrinsic subtypes](#)” have been identified, distinguished by molecular mechanisms, with differences in malignancy and patient outcome ([Parker *et al.*, 2009](#); [Perou *et al.*, 2000](#)). Conversely, common molecular mechanisms may be shared between cancers across tissue types as discovered by the “[Pan Cancer](#)” TCGA project, which combined [molecular profiles](#) across tissue types ([Weinstein *et al.*, 2013](#)). [Molecular subtypes](#) could feasibly be included in clinical testing as a panel of biomarkers for diagnosis, monitoring drug response, or predicting risk of recurrence. As these [molecular subtypes](#) and genetic aberrations specific to cancers have been identified, there is an increasingly clear need for further development of [treatments](#) that target them.

Gene expression can be used to characterise breast cancers. The “intrinsic subtypes” identified were characterised by estrogen receptor, *HER2*, and basal, epithelial signalling (Perou *et al.*, 2000). The expression profiles were similar across independent samples of the same tumour or the same patient and therefore represent the molecular state of a tumour. The molecular intrinsic subtypes “luminal A”, “luminal B”, “HER2-enriched”, “basal-like”, and “normal-like” have been replicated across microarray studies (Hu *et al.*, 2006), with their relevance to prognosis demonstrated, and a 50-gene subtype predictor developed (Parker *et al.*, 2009; Sørlie *et al.*, 2001). Despite specific differences in subtyping, there is widespread agreement that distinguishing luminal, HER2-enriched, and triple negative tumours has prognostic importance for patients (Dai *et al.*, 2015). The “Pan Cancer” The Cancer Genome Atlas project (discussed in Section 1.1.3.2) demonstrates the importance of molecular similarities and differences between cancers across cancer tissue types (Weinstein *et al.*, 2013).

Gatza *et al.* (2010) used gene signatures for 18 cellular pathways in breast cancer to define subtypes with distinct molecular pathway activity. A “metagene” is a measure pathway activation (derived from eigenvectors or principal components) which gives a consistent signal of gene expression (Anjomshoaa *et al.*, 2008; Huang *et al.*, 2003; Nagalla *et al.*, 2013). Unsupervised hierarchical clustering defined subtypes with common pathway activity, despite variation in mutations. These subtypes intrinsic subtypes and provide finer molecular stratification with a functional basis (Gatza *et al.*, 2014; Parker *et al.*, 2009). The subtypes with shared pathway activity have similar molecular characteristics (such as DNA copy number) and clinical properties including prognosis.

1.1.4.4 Targeted Therapeutics and Pharmacogenomics

Targeted therapies with specificity against a molecular target are examples of precision cancer medicine. Molecular targets can be tested in laboratory conditions with RNA interference (RNAi) or pharmacological agents (Fece de la Cruz *et al.*, 2015). Identification of molecular targets is important for developing novel anti-cancer treatments along with validation and drug testing. For oncogenic mutations, the recurrent mutant variant or over-expressed gene can be directly inhibited, however, oncogenes with high homology to other genes or tumour suppressor genes are not amenable to direct targeting (Kaelin, Jr, 2009). Targeted anticancer therapeutics can exploit complex interactions to distinguish normal and cancerous cells which may benefit from studies of gene regulation or interaction networks (Hopkins, 2008). Targeted therapeutics have already been successfully applied as monoclonal antibodies against oncogenes, such as HER2 in breast cancer (Miles, 2001).

1.1.5 Systems and Network Biology

Driver [mutations](#) in [oncogenes](#) and [tumour suppressor](#) genes do not occur in isolation. The genetic interactions, regulatory and cellular signalling, and metabolic reactions are inter-related and may each be perturbed by aberrations in gene function occurring in [cancers](#). These relationships can be represented by biological networks of connected pairs of genes with a relationship. Due to the complexity of a cell, these molecular networks are very large, consisting of thousands of [nodes](#) comprised by genes or proteins.

The properties of large [networks](#) were first studied by constructing random [networks](#) by randomly linking a fixed number of [nodes](#) ([Erdős and Rényi, 1959, 1960](#)). Despite the random nature of these [networks](#), properties such as their connectivity were well characterised. The [vertex](#) degree (number of partners for each [node](#)) of their random [networks](#) followed a Poisson distribution, however this property does not hold in nature. Thus natural [networks](#) are non-random or not formed in this way ([Barabási and Oltvai, 2004](#)).

This work formed the foundation for studying complex [networks](#) ([van Steen, 2010](#)), which model features of observed [networks](#) not found in Erdős and Rényi's random [networks](#) ([Erdős and Rényi, 1959, 1960](#)). The [small world](#) property, made popular by findings in social [networks](#) ([Travers and Milgram, 1969](#)), is the remarkably short path lengths between any [nodes](#) in a [small world network](#). A [small world network](#) is well-connected with a characteristic path length (the average length of [shortest paths](#) between all pairs of [nodes](#)) proportional to the logarithm of the number of [nodes](#). [Watts and Strogatz \(1998\)](#) developed a model of random rewiring of a regular [network](#) to construct random [networks](#) with the [small world](#) property and a high clustering coefficient. While these properties are more representative of [networks](#) occurring in nature, their model was limited by the degree distribution which converges to a Poisson distribution as it is rewired ([Barrat and Weigt, 2000](#)). The [vertex](#) degree distribution of naturally occurring [networks](#) often follows a power law distribution with most [nodes](#) having far fewer connections than average and a small subset of highly connected [network](#) 'hubs' ([Barabási and Albert, 1999](#)).

[Barabási and Albert \(1999\)](#) constructed a [network](#) model in an entirely different way to randomly generate [scale-free networks](#) which have a power law degree distribution. They constructed random [networks](#) by preferential attachment, modelling growth of a [network](#) by sequentially adding [nodes](#) with [links](#) to existing [nodes](#). The [scale-free](#) nature of the random [networks](#) was ensured by adding new [nodes](#) with an increasing probability

of attachment to an existing [node](#) if it had a higher degree. These [networks](#) successfully captured the [scale-free](#) nature of many observed [networks](#) with short characteristic path length and low eccentricity resulting in super [small worlds](#) (Barabási and Albert, 1999).

High-throughput technologies such as [siRNA](#) screens, two-hybrid screens, [microarrays](#) and massively parallel sequencing have generated [genomes-scale](#) data and enabled analysis of biological [networks](#) (Barabási and Oltvai, 2004; Boone *et al.*, 2007; Goodwin *et al.*, 2016). Molecular networks are biological networks consisting of biological molecules including genes, transcripts (with non-coding and [microRNAs](#)), or proteins related by known interactions and gene regulatory or metabolic [pathways](#). Many types of molecular networks can be constructed, depending on the biological application (). [Synthetic genetic interactions](#) are relatively unexplored within molecular networks and may lead to better understanding of the role of gene functions in cellular function and disease. [High-throughput screens](#) in humans, mammals, and non-model organisms are costly and labour-intensive (Fece de la Cruz *et al.*, 2015). Computational approaches with effective predictive models are therefore a more feasible alternative to study the connectivity of a biological [network](#) in a complex metazoan cell at the [genomes-scale](#).

1.2 Synthetic Lethal Cancer Medicine

[Synthetic lethality](#) has vast potential to improve cancer medicine by expanding application of [targeted therapeutic](#) to include inactivation of [tumour suppressors](#) and genes that are difficult to target directly. [Synthetic lethal](#) interactions are also studied for gene function and drug mode-of-action in model organisms. This Section introduces the concept of [synthetic lethality](#) as it was originally conceived and how it has been adopted conceptually in cancer research. Detecting these interactions at scale and interpreting them is the focus of this thesis, hence we start with an overview of the concepts involved, initial work on the interaction, and the rationale for applications to cancer. Specific investigations into [synthetic lethality](#) in cancer, detection by experimental screening, and prediction by computational analysis will then be reviewed.

1.2.1 Synthetic Lethal Genetic Interactions

Genetic interactions are a core concept of molecular biology, discovered among earliest investigations of Mendelian genetics, and have received revived interest with new technologies and potential applications. [Biological epistasis](#) is the effect of an [allele](#) at one locus “masking” the phenotype of another locus (Bateson and Mendel, 1909). [Statistical epistasis](#) is where there is significant disparity between the observed and ex-

pected phenotype of a double **mutant**, compared to the respective phenotypes of single **mutant** and the **wild-type** (Fisher, 1919). Fisher’s **definition** lends itself to quantitative traits and more broadly encompasses **synthetic genetic interactions**. These have become popular for studies in yeast genetics and cancer drug design (Boone *et al.*, 2007; Kaelin, Jr, 2005).

SGIs are substantial deviations of growth or viability from the expected null **mutant** phenotype (of an organism or cell) assuming additive (deleterious) effects of the single **mutant**. The double **mutant** does not necessarily have either of the single **mutant** phenotypes (as shown for cellular growth phenotypes in Figure 1.1). Most **SGIs** are more viable than either single **mutant** or less viable than the expected double **mutant**. Mutations are “synergistic” in negative **SGI** with more deviation from the **wild-type** than expected. Formally, “**synthetic sick**” (**SSL**) and “**synthetic lethal**” (**SL**) interactions are negative **SGIs** giving growth inhibition and complete inviability respectively. In cancer research, **synthetic lethality** more broadly describes any negative **SGI** with specific inhibition of a **mutant** cell, including **SSL** interactions. Mutations are “alleviating” in positive **SGI** with less deviation from the **wild-type** than expected. For viability, “**suppression**” (**SS**) and “**rescue**” (**SR**) are positive **SGIs** giving at least partial restoration of **wild-type** growth from single **mutant** with growth impairment and lethal phenotypes respectively. Negative **SGIs** were markedly more common than positive **SGIs** in a number of studies in model systems (Boucher and Jenna, 2013; Tong *et al.*, 2004).

Figure 1.1: **Synthetic genetic interactions.** Impact of various negative and positive **SGIs**: negative interactions involve deleterious (sick) or inviable (lethal) phenotypes whereas positive interactions involve restoring viability by masking or suppressing the other **mutation** or complete rescue of the **wild-type** phenotype. Figure adapted from (Costanzo *et al.*, 2011) concerning growth viability fitness in yeast.

1.2.2 Synthetic Lethal Concepts in Genetics

Synthetic lethal genes are generally regarded to arise due to **functional redundancy** (Boone *et al.*, 2007). Due to the functional level of **SGIs**, **synthetic lethal** genes do not need to directly interact, nor be expressed in the same cell or at the same developmental stage: serving related functions is sufficient to affect cell (or organism) viability and be relevant to drug-mode-of-action cancer biology. Combined loss of genes performing an **essential** or important function in a cell are therefore deleterious. **Synthetic lethal** gene pairs are therefore pairwise **essential** with “**induced essentiality**”: each **synthetic lethal** gene becomes **essential** to the cell upon loss of the other (Ashworth *et al.*, 2011; Kaelin, Jr, 2005).

Since **synthetic lethal** gene partners can be affected by extracellular stimuli such as chemicals, essentiality of **synthetic lethal** genes can be induced by the environment of a cell. An environmental stress condition may inhibit one or the other **synthetic lethal** gene, such as exposure to chemicals, in which case the **synthetic lethal** partner gene is “conditionally essential” (Hillenmeyer, 2008). Thus the evolutionary rationale for the abundance of **SGIs** (compared to the surprisingly low number of **essential** genes) in a Eukaryotic **genomes** can be attributed to genetic **functional redundancy** and network **robustness** of a cell which are advantageous to survival.

Biological functions are typically performed by a **pathway** of genes (or their products). **Synthetic lethal** genes occur within the same biological **pathway** and between them (Boone *et al.*, 2007; Costanzo *et al.*, 2010; Kelley and Ideker, 2005). Many genes of the same **pathway** may be functionally interchangeable, **synthetic lethal** partners of a particular gene. Therefore biological **pathways** can exhibit **induced essentiality** with loss of the **synthetic lethal** partner gene and **synthetic lethality** may occur at **pathway** level or in a gene regulation network.

1.2.3 Synthetic Lethality in Model Systems

Genetic **high-throughput screens** have identified unexpected, functionally informative, and clinically relevant **synthetic lethal** interactions; including **synthetic lethal** partners of genes recurrently mutated in cancer or attributed to **familial** early-onset cancers (Lord *et al.*, 2015). While screening presents an appealing strategy for **synthetic lethal** discovery, computational approaches are becoming popular as an alternative or complement to experimental methods to overcome inherent bias and limitations of experimental screens. An array of recently developed computational methods (Jerby-Arnon *et al.*, 2014; Lu *et al.*, 2015; Tiong *et al.*, 2014; Wang and Simon, 2013; Wappett, 2014)

show the need for [synthetic lethal](#) discovery in the fundamental genetics and translational cancer research community. However, many existing computational methods are not suitable for queries of [genomic](#) data for interacting partners of a particular gene, as (1) they have been applied pairwise across the [genomes](#), (2) they do not have software released to apply the methodology, or (3) they lack statistical measures of error for further analysis. A robust prediction of gene interactions is an effective and practical approach at a scale of the entire [genomes](#) for ideal translational applications, analysis of biological systems, and constructing functional gene networks.

1.2.3.1 Synthetic Lethal Pathways and Networks

SGIs are common in [genomes](#), four-fold more interactions were detected with [synthetic gene array \(SGA\)](#) mating screens than [protein-protein interactions](#) detected with yeast-2-hybrid (Tong *et al.*, 2004). The SGI network was [scale-free](#) and had a low average [shortest path](#) length, as expected for a complex biological network (Barabási and Oltvai, 2004). Highly connected “hub” genes with the highest number of [links](#) ([vertex degree](#)) are functionally important with many negative SGI hubs involved in cell cycle regulation, and many positive SGI hubs involved in translation (Baryshnikova *et al.*, 2010b; Costanzo *et al.*, 2010). Negative SGIs were far more common than positive SGIs, with synthetic gene loss being more likely to be deleterious to cell than advantageous, which indicates that [synthetic lethality](#) may be comparably easier to detect than other SGIs.

[Essential pathways](#) are highly buffered, with five-fold more interactions than other SGIs, consistent with strong selection for survival, as found with conditional and partial mutations in [essential](#) genes (Davierwala *et al.*, 2005). This SGI network had [scale-free](#) topology and rarely shared interactions with the protein-protein interaction network. These networks are related by an “orthogonal” relationship: shared partners in one network tend to be themselves connected directly in the other network. Essential genes were likely to have closely related functions, whereas non-[essential](#) networks were relatively more inclined to have SGIs between distinct biological [pathways](#).

1.2.3.2 Evolution of Synthetic Lethality

There is poor conservation of specific SGIs between *S. cerevisiae* and *S. pombe* with 29% of the interactions tested in both distantly related species being conserved between them (Dixon *et al.*, 2008). The remaining interactions show high species-specific differences, however, many of the species-specific interactions were still conserved between biological [pathways](#), protein complexes, or protein-protein interaction modules.

Similarly, conservation of [pathway](#) redundancy was also found between Eukaryotes (*S. cerevisiae*) and prokaryotes (*E. coli*) (Butland *et al.*, 2008). Negative [SGIs](#) were more likely to be conserved between biological [pathways](#), whereas positive [SGIs](#) were more likely to be conserved within a [pathway](#) or protein complex (Roguev *et al.*, 2008).

A modest 5% of interactions were conserved between unicellular (*S. cerevisiae*) and multicellular (*C. elegans*) organisms. However, the nematode [SGI](#) network had similar [scale-free](#) topology and modularity despite differences in methodology: metazoan [synthetic lethal](#) screens with [RNA interference](#) ([RNAi](#)) are incomplete knockouts, whereas screening null [mutations](#) is feasible in yeast (Bussey *et al.*, 2006). The nematode [SGI](#) screen identified network hubs with important interactions to orthologues of known human disease genes (Lehner *et al.*, 2006). Despite the lack of direct conservation of [SGIs](#) between yeasts and nematode worms, [genetic redundancy](#) was consistent with an “[induced essentiality](#)” model of [SGIs](#) where gene functions are conserved with network restructuring over evolutionary change (Tischler *et al.*, 2008).

While nematode models are more closely related to human cells which are also screened with [RNAi](#), cancer cells can present growth and viability phenotypes more comparable to yeast models. Therefore findings from both [SGA](#) and [RNAi](#) models are relevant to understanding human and cancer cells. [RNAi](#) has also been applied to human and mouse cancer cells with [short interfering RNA](#) ([siRNA](#)) in cell culture and genetic screening experiments. These findings suggest that [SGI](#) network “rewiring” is a concern for identifying specific [synthetic lethal](#) interactions in cancer as specific [synthetic lethal](#) genes may vary between genetic backgrounds. Thus it is expected at a [pathway](#) approach will be more robust in the context of evolution, patient variation, tumour heterogeneity, or disease progression.

1.2.4 Synthetic Lethality in Cancer

Loss of function occurs in many genes in cancers, including [tumour suppressors](#), yet few interventions target such [mutations](#) compared to targeted therapies for gain of function [mutation](#) in [oncogenes](#) (Kaelin, Jr, 2005). [Synthetic lethality](#) is a powerful design strategy for therapies selective against loss of gene function with potential for application against a range of genes and diseases (Fece de la Cruz *et al.*, 2015; Kaelin, Jr, 2009). When genes are disrupted in cancers, the [induced essentiality](#) of [synthetic lethal](#) partners presents a vulnerability that may be exploited for anti-cancer therapy. Since [synthetic lethality](#) affects cellular viability by indirect functional relationships between genes, it is suitable for indirectly targeting [mutations](#) in cancers via [synthetic lethal](#)

partners with **targeted therapeutic**. These have could be highly specific against cancer cells (with the target **mutation**) over non-cancer cells (with a functional compensating gene). Analogous to “**oncogene addiction**”, where cancer cells adapt to particular oncogenic growth signals and become reliant on them to remain viable (Luo *et al.*, 2009; Weinstein, 2000), **synthetic lethal** partners of inactivated **tumour suppressors** are required to maintain cancer cell viability and proliferation. As such cancers are subject to “**non-oncogene addiction**” and these genes are feasible anti-cancer drug targets.

Figure 1.2: **Synthetic lethality in cancer**. Rationale of exploiting **synthetic lethality** for specificity against a **tumour suppressor** gene (e.g., *CDH1*) while other cells are spared under the inhibition of a partner gene.

The **synthetic lethal** approach to cancer medicine is most amenable to loss of function **mutations** in **tumour suppressor** genes, where it would feasibly be effective against any loss of function **mutation** across the **tumour suppressor** with a viable **synthetic lethal** partner gene (as shown in Figure 1.2). However, the approach may also be suitable for cases where cancer cells have **mutations** where the normal function of the gene is disrupted such as if it were over-expressed (“**synthetic dosage lethality**”) or if an oncogenic **mutation** interfered with the function of the proto-oncogene. Thus **synthetic lethality** makes it feasible to target a range of cancer-specific **mutations** with **targeted therapeutic**, including inactivated **tumour suppressor** genes. **synthetic lethality** may also enable distinguishing highly homologous **oncogenes** by functional differences by targeting their **synthetic lethal** partners.

1.2.5 Clinical Impact of Synthetic Lethality in Cancer

The [synthetic lethal](#) interaction of *BRCA1* or *BRCA2* with *PARP1* in breast cancer is an example of how gene interactions are important in cancer and these discovery of these interactions has lead to translation to the clinic. These genetic interactions enable specific targeting of [mutations](#) in *BRCA1* or *BRCA2* [tumour suppressor](#) genes with Poly-ADP-ribose polymerase (PARP) inhibitors by inducing [synthetic lethality](#) in breast cancer ([Farmer *et al.*, 2005](#)). PARP inhibitors were one of the first [targeted therapeutic](#) against a [tumour suppressor mutation](#) to exhibit success in clinical trials.

BRCA1/BRCA2 and *PARP1* genes demonstrate the application of the [synthetic lethal](#) approach to cancer therapy ([Ashworth, 2008](#); [Kaelin, Jr, 2005](#)). *BRCA1* and *BRCA2* are homologous DNA repair genes, widely known as [tumour suppressors](#); [mutation](#) carriers have substantially increased risk of breast (risk by age 70 of 57% for *BRCA1* and 59% for *BRCA2*) and ovarian cancers (risk by age 70 of 40% for *BRCA1* and 18% for *BRCA2*) ([Chen and Parmigiani, 2007](#)). The *BRCA1* or *BRCA2* genes, which usually repair DNA or destroy the cell if it cannot be repaired, have inactivating [somatic mutations](#) in some [familial](#) and [sporadic](#) cancers. Poly-ADP-ribose polymerase (PARP) genes are [tumour suppressor](#) genes involved in base excision DNA repair. Loss of PARP activity results in single-stranded DNA breaks. However, *PARP1*^{-/-} knock-out mice are viable and healthy indicating low toxicity from PARP inhibition ([Bryant *et al.*, 2005](#)).

[Bryant *et al.* \(2005\)](#) showed that *BRCA2* cells were sensitive to PARP inhibition by [siRNA](#) of *PARP1* or drug inhibition (which targets *PARP1* and *PARP2*) using Chinese hamster ovary cells, MCF7 and MDA-MB-231 breast cell lines. This effect was sufficient to kill mouse tumour xenografts and showed high specificity to *BRCA2* deficient cells in culture and xenografts. [Farmer *et al.* \(2005\)](#) replicated these results in embryonic stem cells and showed that *BRCA1* cells were also sensitive to PARP inhibition relative to the [wild-type](#) with [siRNA](#) and drug experiments in cell culture and drug activity against *BRCA1* or *BRCA2* deficient embryonic stem cell mouse xenografts. They found evidence that PARP inhibition causes DNA lesions, usually repaired in [wild-type](#) cells, which lead to chromosomal instability, cell cycle arrest, and induction of apoptosis in *BRCA1* or *BRCA2* deficient cells. The combined loss of DNA repairs [pathways](#) gives a plausible mechanism for an effective anti-cancer treatment.

Thus PARP inhibitors could be applied with clinical use against *BRCA1* or *BRCA2* [mutations](#) in both [hereditary](#) and [sporadic](#) cancers ([Ashworth, 2008](#); [Kaelin, Jr, 2005](#)). PARP inhibition has been found to be effective in ovarian cancer patients carrying

BRCA1 or *BRCA2* mutations and some patient without these mutations, suggesting synthetic lethality between PARP and other DNA repair pathways (Ström and Helleday, 2012). This supports the potential for PARP inhibition as a chemopreventative alternative to prophylactic surgery for high-risk individuals with *BRCA1* or *BRCA2* mutations (Ström and Helleday, 2012). Hormone-based therapy has also been suggested as a chemopreventative in such high-risk individuals and aromatase inhibitors have completed phase I clinical trials for this purpose (Bozovic-Spasojevic *et al.*, 2012). Ström and Helleday (2012) also postulate increased efficacy of PARP inhibitors in the hypoxic DNA-damaging tumour micro-environment.

A PARP inhibitor, olaparib, showed fewer adverse effects than cytotoxic chemotherapy and anti-tumour activity in various clinical trials against *BRCA1* or *BRCA2* deficient familial or sporadic breast, ovarian, and prostate cancers (Audeh *et al.*, 2010; Fong *et al.*, 2009, 2010; Tutt *et al.*, 2010). This treatment has a favourable therapeutic window and similarly low toxicity between mutation carriers of *BRCA1* or *BRCA2* mutations and sporadic cases. These PARP inhibitors have been FDA approved for some cancers McLachlan *et al.* (2016), are effective against germline mutation and sporadic *BRCA1* or *BRCA2* mutations, and are a potential prevention alternative to prophylactic surgery for high-risk mutation carriers Ström and Helleday (2012).

This demonstrates the clinical impact of a well characterised system of synthetic lethality with known cancer risk genes. Synthetic lethality has the benefit of being effective against inactivation of tumour suppressor genes by any means, broader than targeting a specific oncogenic mutation (Kaelin, Jr, 2005). The targeted therapy is effective in both sporadic and hereditary *BRCA1* or *BRCA2* deficient tumours acting against an oncogenic molecular aberration across several tissues.

1.2.6 High-throughput Screening for Synthetic Lethality

RNA interference (RNAi) technologies have enabled extensive investigations of genetic redundancy in mammalian experimental models including testing experimentally for synthetic lethality (Fraser, 2004). Synthetic lethal RNAi screens are performed, using short interfering RNA (siRNA) or short hairpin RNA (shRNA) to target specific genes in isogenic cells. Identifying synthetic lethality is crucial for studying gene function, drug mechanisms, and design novel therapies (Lum *et al.*, 2004). Candidate selection of synthetic lethal gene pairs relevant to cancer has shown some success but is limited because interactions are difficult to predict; they can occur between seemingly unrelated pathways in model organisms (Costanzo *et al.*, 2011). While biologically informed

hypotheses have had some success in [synthetic lethal](#) discovery ([Bitler *et al.*, 2015](#); [Bryant *et al.*, 2005](#); [Farmer *et al.*, 2005](#)), interactions occurring indirectly between distinct [pathways](#) would be missed ([Boone *et al.*, 2007](#); [Costanzo *et al.*, 2011](#)). Scanning the entire [genomes](#) for interactions against a clinically relevant gene is an emerging strategy being explored with [high-throughput screens](#) ([Fece de la Cruz *et al.*, 2015](#)) and computational approaches ([Boucher and Jenna, 2013](#); [van Steen, 2012](#)).

Experimental [screening](#) for [synthetic lethality](#) is an appealing strategy for wider discovery of functional interactions *in vivo* despite many potential sources of error which must be considered. The [synthetic lethal](#) concept has both genetic and pharmacological screening applications to cancer research. Genetic screens, with [RNAi](#) to discover the specific genes involved, inform development of targeted therapies with a known mode of action, anticipated mechanisms of resistance, and biomarkers for treatment response. [RNAi](#) is a transient knockdown of [gene expression](#) more similar to the effect of drugs than complete gene loss and is more representative of disease than model organisms ([Bussey *et al.*, 2006](#)). The [RNAi](#) gene knockdown process has inherent toxicity to some cells, potential off-target effects, and issues with a high false positive rate. Therefore, it is important to validate any candidates in a secondary screen and replicate knockdown experiments with a number of independent [shRNAs](#). [Genetic screens](#) have potential for quantitative gene disruption experiments to selectively target over-expressed genes in cancer via [synthetic dosage lethality](#). While powerful for understanding fundamental cellular function, analysis of isogenic cell lines is inherently limited by assuming only a single [mutation](#) differs between them and cannot account for diverse genetic backgrounds or tumour heterogeneity ([Fece de la Cruz *et al.*, 2015](#)). Genetic screens can thus identify targets to develop, or can repurpose targeted therapies for disease, but alone will not directly identify a lead compound to develop for the market or for clinical translation.

[Chemical screens](#) are immediately applicable to the clinic, as they are directly screening for selective lead compounds with suitable pharmacological properties. However, chemical screens lack a known mode of action, may affect many targets, and screen a narrow range of genes with existing drugs. With either approach there are still many challenges to translating candidates into the clinic. Identifying specific target genes may contribute to overcoming such challenges, which can be approached with genetic screens and computational alternatives. Screening methods have proven a fruitful area of research, despite being costly, laborious, and having many different

sources of error. These limitations suggest a need for complementary computational approaches to [synthetic lethal](#) discovery.

1.2.6.1 Synthetic Lethal Screens

Synthetic lethal screens have been conducted for cancer gene in a variety of [cancers](#). These have found [synthetic lethality](#) of *PIM1* over-expression with *PLK1* inhibition in prostate cells ([van der Meer et al., 2014](#)), *FH* null mutations (involved in [Hereditary leiomyomatosis and renal cell carcinoma \(HLRCC\)](#)) with inhibition of adenylate cyclases ([Boettcher et al., 2014](#)), and *WEE1* inhibitor treatment with knockdown of checkpoint kinases, Fanconi anaemia, and homologous recombination in colorectal cells ([Aarts et al., 2015](#)). These results show include genes that have been found to be co-expressed in cancers, are consistent with those identified in the literature, and that were successfully validated with [RNAi](#) and drug experiments. These demonstrate that [synthetic lethal](#) screening can identify partner genes with clinical relevance as biomarkers, therapeutic targets, or conferring sensitivity to existing treatments. These are of particular importance for familial cancer syndromes ([Boettcher et al., 2014](#); [Telford et al., 2015](#)).

[Hereditary diffuse gastric cancer \(HDGC\)](#) is a cancer syndrome of predisposition to early-onset malignant stomach and breast cancers attributed to [mutations](#) in [E-cadherin](#), encoded by *CDH1* (as discussed in [Section 1.3](#)). [Telford et al. \(2015\)](#) performed an [RNAi](#) screen on MCF10A breast cells for [synthetic lethality](#) with *CDH1*. They found enrichment of [G protein coupled receptors](#) and cytoskeletal gene functions. The results were consistent with a concurrent drug compound screen with several candidates validated by lentiviral [shRNA](#) gene knockdown and drug testing including inhibitors of [Janus kinase \(JAK\)](#), [histone deacetylase \(HDAC\)](#), [phosphoinositide 3-kinase \(PI3K\)](#), aurora kinase, and tyrosine kinases. Therefore the [synthetic lethal](#) strategy has potential for clinical impact against [HDGC](#), with an interest in interventions with low adverse effects for [chemoprevention](#), including repurposing existing approved drugs for activity against *CDH1* deficient cancers.

The examples above show that high-throughput screens are an effective approach to discover [synthetic lethality](#) in cancer with a wide range of applications. Screens are more comprehensive than hypothesis-driven candidate gene approaches and successfully find known and novel [synthetic lethal](#) interactions with potential for rapid clinical application. They have the power to test mode of action of drugs, find unexpected [synthetic lethal](#) interactions between [pathways](#), or identify effective treatment strategies without needing a clear mechanism. However, [synthetic lethal](#) screens are costly,

labour-intensive, error-prone, and biased towards genes with effective RNAi knockdown libraries. Limited genetic background, lethality to wild-type cell during gene knock-down, off-target effects, and difficulty replicating synthetic lethality across different cell lines, tissues, laboratories, or conditions stems from a high false positive rate and a lack of standardised thresholds to identify synthetic lethality in a high-throughput screen. Therefore there is a need for replication, validation, and alternative approaches to identify synthetic lethal candidates. In addition, varied conditions across experimental screens and differences between RNAi and drug screens makes meta-analysis extremely challenging.

Genome-scale synthetic lethal experiments (across gene pairs) are not feasible, even in model organisms, and they typically focus on specific gene candidates or the partners of a gene of interest (such as importance in health). Therefore a computational approach is more suitable for this task and may further augment experimental screening to replicate screen candidates beyond experimental models.

1.2.7 Computational Prediction of Synthetic Lethality

1.2.7.1 Bioinformatics Approaches to Genetic Interactions

Prediction of gene interaction networks is a feasible alternative to high-throughput screening, and has both biological importance and clinical relevance. There are many existing methods to predict gene networks, as reviewed by van Steen (2012) and Boucher and Jenna (2013) and summarised in Table 1.1. However, many of these methods have limitations, including the requirement for existing SGI data, several data inputs, and reliability of gene function annotation. Many of the existing methods also assume conservation of individual interactions between species, which has been found not to hold in yeast studies (Dixon *et al.*, 2008). Tissue specificity is important in gene regulation and gene expression, which are used as predictors of genetic interaction. However, tissue specificity of genetic interactions cannot be explored in yeast studies and has not been considered in many studies of multicellular model organisms, human networks, or cancers. Similarly, investigation into tissue specificity of PPIs, an important predictor of genetic interactions, is difficult given that high-throughput two-hybrid screens occur out of cellular context for multicellular organisms (Brückner *et al.*, 2009).

There are existing computational methods for predicting synthetic lethal gene pairs in humans, with a specific emphasis on cancer (as summarised in 1.2). While these demonstrate the power and need for predictions of synthetic lethality in human and

cancer contexts, limitations of previous methods could be met with a different approach. Existing computational approaches to synthetic lethal prediction are often difficult to interpret or replicate for new genes, or are reliant on data types not available for a wider range of genes to test.

1.2.7.2 Comparative Genomics

A comparative [genomic](#) approach by [Deshpande *et al.* \(2013\)](#) used the results of well characterised high-throughput [mutation](#) screens in *S. cerevisiae* as candidates for [synthetic lethality](#) in humans ([Baryshnikova *et al.*, 2010a](#); [Costanzo *et al.*, 2010, 2011](#); [Tong *et al.*, 2001, 2004](#)). Yeast [synthetic lethal](#) partners were compared to human orthologues to find cancer relevant [synthetic lethal](#) candidate pairs with direct therapeutic potential. Proposed as a complementary approach to [siRNA](#) screens, approximately 24,000 of the 116,000 negative [SGI](#) in yeast ([Costanzo *et al.*, 2011](#)) were matched to human orthologues, with over 500 involving a [cancer gene](#) ([Futreal *et al.*, 2004](#)). Under strict criteria of one-to-one orthologues, large effect size and significant interaction in yeast data, 1522 interactions were identified with 70 involving [cancer genes](#). Of the 21 gene interactions tested with pairs of [siRNA](#) in IMR1 fibroblast cells, 6 exhibited [synthetic lethal](#) effects. The two strongest interactions (*SMARCB1* with *PSMA4* and *ASPSCR1* with *PSMC2*) were successfully validated by protein analysis of human cells and replication with tetrad analysis for yeast orthologues.

Another approach to systematic [synthetic lethality](#) discovery specific to human cancer (in contrast to the plethora of yeast [synthetic lethality](#) data) was to build a database as done by [Li *et al.* \(2014\)](#). In their relational database, called “Syn-lethality”, they have curated both known experimentally discovered [synthetic lethal](#) pairs in humans (113 pairs) from the literature and those predicted from [synthetic lethality](#) between orthologous genes in *S. cerevisiae* yeast (1114 pairs). This knowledge-based database is the first dedicated to human cancer [synthetic lethal](#) interactions and integrates gene function annotation, [pathway](#) and molecular mechanism data with experimental and predicted [synthetic lethal](#) gene pairs. This combination of data sources is intended to tackle the trade-off between more conclusive [synthetic lethal](#) experiments in yeast and more clinically relevant [synthetic lethal](#) experiments in human cancer models, such as [RNAi](#), especially when high-throughput screens are costly and prone to false positives in either system and are difficult to replicate across gene backgrounds. This database centralises a wealth of knowledge scattered in the literature including cancer relevant genes, including the previously mentioned interactions of *BRCA1* and *BRCA2* with *PARP1*, and *TP53* with *WEE1* and *PLK1*, although the computational methodology was not released and was limited to 647 human genes. Their future directions were promising, such as constructing networks of known [synthetic lethality](#), applying known [synthetic lethality](#) to cancer treatment, data mining, replicating the approach for [synthetic lethality](#) in model organisms, signalling pathways, and developing a complete

global network in human cancer or yeast (both of which are still incomplete with experimental data), some of which has been implemented in “SynLethDB” (Guo *et al.*, 2016).

MetaSL (Meta-Analysis)	Wu <i>et al.</i> (2014)	MetaSL

Machine learning approaches have also been explored for [synthetic lethal](#) discovery (Babyak, 2004; Lee and Marcotte, 2009). Due to concerns that these may be subject to overfitting or noise, Wu *et al.* (2014) developed a meta-analysis method (based on the machine learning methods in Table 1.3). They focused on [synthetic lethal](#) gene pairs relevant to developing selective drugs against human cancer, building upon their previous database (Li *et al.*, 2014). Their “metaSL” approach utilises [genomic](#), proteomic and annotation data and had a high statistical performance in yeast data with an [area under receiver operating characteristic \(AUROC\)](#) of 0.871 (as described in Section 2.3.5.1). They predicted orthologous [synthetic lethal](#) partners in human data were not experimentally validated but some were relevant to cancer such as *EGFR* with *PRKCZ*.

Computational approaches scale-up across the [genomes](#) at lower cost than experimental screen (Wu *et al.*, 2014). Wu *et al.* (2014) provided their most supported interactions online but the method is not available for analysis of other genes. Syn-Lethality (Li *et al.*, 2014) and MetaSL (Wu *et al.*, 2014) demonstrate the value of computational approaches to [synthetic lethality](#) but omit many genes of importance in cancer, such

as *CDH1*. Accordingly, there remains a need to enable biological researchers to query further genes and do so in a particular tissue or genetic background.

There is also concern for analyses based on yeast data that many [synthetic lethal](#) interactions may not be conserved between species ([Dixon *et al.*, 2009](#)), although interactions between [pathways](#) may be more comparable. It is unsurprising that many of the interactions identified were not experimentally validated. There have been many gene duplications in the separate evolutionary histories of humans and yeast which may lead to differences in [genetic redundancy](#). Yeast cells are not an ideal human cancer model because they do not have tissue specificity, multicellular gene regulation, or orthologues to several known [cancer genes](#) such as p53 ([Guaragnella *et al.*, 2014](#)). Although these studies have tried to anticipate these issues with stringent criteria such as requiring one-to-one orthologues ([Deshpande *et al.*, 2013](#); [Heiskanen and Aittokallio, 2012](#); [Kranthi *et al.*, 2013](#)), there remains the possibility that changes in gene function may affect whether these are solely redundant such as if functions had co-evolved without sequence homology. Many genes will also be excluded since they lack homologues in yeast, the corresponding experimental data, or having paralogues in either species. Thus conservation of yeast interactions is not an ideal strategy and analysis of human data directly for comparison with human experimental data will be the focus of this thesis.

1.2.7.3 Analysis and Modelling of Protein Data

[Kranthi *et al.* \(2013\)](#) took a network approach to discovery of [synthetic lethal](#) candidate selection applying the concept to “centrality” to a human [PPI](#) network involving interacting partners of known [cancer genes](#). The effect of removing pairs of genes on connectivity of the network was used as a surrogate for viability which is supported by observations that the [PPI](#) and [synthetic lethal](#) networks are orthogonal in *S. cerevisiae* studies ([Tong *et al.*, 2004](#)). They showed that the human cancer protein interaction network derived protein interactions and cancer gene databases ([Futreal *et al.*, 2004](#); [Higgins *et al.*, 2007](#); [Keshava Prasad *et al.*, 2009](#)), consisting of 1539 proteins and 6471 interactions, exhibits the power law distribution expected of a [scale-free synthetic lethal](#) network with high connectivity (average [vertex](#) degree of 23.67 and network efficiency of 0.2952). Their top 100 candidate interactions included interactions of the [tumour suppressor](#) *TP53* with *BRCA1*, *CDKNA1*, *CDKNA2*, *MET*, and *RB1* which have been detected by prior studies. The gene pairs were often observed to be in the same or a plausible compensatory pathway. This demonstrated that [network](#) structure

is important in the biological functions of cancers and could be exploited for targeting *TP53* loss of function mutations.

However, the approach of Kranthi *et al.* (2013) was limited to known cancer genes and is not applicable to genes that do not have PPI data. Other nucleotide sequencing data types are more commonly available for cancer studies at a genomic scale. Of further concern is that the results were enriched for p53 synthetic lethal partners, which is relevant to many cancers but this genomes-wide approach did not detect many other cancer genes due to the extent of multiple testing. This enrichment may be due to the known drastic effect of removing p53 itself from the network as a highly connected, master regulator, and cancer driving tumour suppressor gene. The focus on cancer genes is useful for translation into therapeutics but does not account for variable genetic backgrounds or effect of protein removal on the cellular network.

Focusing on the potential for synthetic lethality to be an effective anti-cancer drug target, Zhang *et al.* (2015) used modelling of signalling pathways to identify synthetic lethal interactions between known drug targets and cancer genes by simulating gene knockdowns. A computational approach was applied to avoid the limitations of experimental RNAi screens such as scale, instability of knockdown, and off-target effects. This ‘hybrid’ method of a data-driven model and known signalling pathways showed potential to predict cell death in single and combination gene knockouts. They used time series protein phosphorylation data (Lee *et al.*, 2012) for 28 signalling proteins and Gene Ontology (GO) pathways (Ashburner *et al.*, 2000; Blake *et al.*, 2015). This approach successfully detected many known essential genes in the human gene essentiality database, known synthetic lethal partners in the Syn-Lethality database (Li *et al.*, 2014), and predicted novel synthetic lethal gene pairs.

These novel results contained many *TP53* and AKT synthetic lethal partners (Zhang *et al.*, 2015), genes known to be important in many cancers. However, these genes also have a severe impact on the signalling pathways in an essentiality analysis of single gene disruptions and large phenotypic changes in cancer (Zhang *et al.*, 2015). This approach is amenable to detect functionally related pathways and protein complexes across the molecular function, cellular component, and biological process annotations provided by Gene Ontology. The results were consistent with the experimental results in the literature but the novel synthetic lethal interactions have yet to be validated. While the mathematical reasoning and algorithms are given, the code was not released to replicate the findings or apply the methodology beyond the signalling pathways analysed by (Zhang *et al.*, 2015). While this is an interesting approach, the

analysis of this thesis will focus on [gene expression](#) and [RNAi](#) data, the widespread availability which allows testing of a broader range of candidate gene pairs.

1.2.7.4 Differential Gene Expression

Differential [gene expression](#) has been explored to predict [synthetic lethal](#) pairs in cancer which would be widely applicable due to the availability of public [gene expression](#) data for many samples and cancer types. Wang and Simon (2013) found differentially expressed genes (by the t-test, adjusted by False discovery rate (FDR)) between tumours with or without functional p53 mutations in TCGA (McLendon *et al.*, 2008) and Cancer Cell Line Encyclopaedia (CCLE) (Barretina *et al.*, 2012) RNA-Seq gene expression data as candidate [synthetic lethal](#) partner pathways of p53. They identified 2, 8, and 21 candidate [synthetic lethal](#) partner genes in 3 [microarray](#) datasets from the NCI60 cell lines, 31 partner genes from the CCLE RNA-Seq data (Barretina *et al.*, 2012), and 50 in TCGA RNA-Seq data (Muzny *et al.*, 2012). *PLK1* was replicated across 4 of these analyses and 17 other genes were replicated across 2 analyses (including *MTOR*, *PLK4*, *MAST2*, *MAP3K4*, *AURKA*, *BUB1* and 6 CDK genes) with many playing a role in cell cycle regulation. This was supported by a drug sensitivity experiment on the NCI60 cell lines which found that cells lacking functional p53 were more sensitive to paclitaxel (which targets *PLK1*, *AURKA*, and *BUB1*). This demonstrated the potential of [gene expression](#) as a surrogate for gene function, and the use of public [genomic](#) data to predict [synthetic lethal](#) gene pairs in cancer. Wang and Simon (2013) advocated for pre-screening of [expression](#) profiles to augment future [RNAi](#) screens, however, their analyses were limited to kinase genes and focused on currently druggable targets, lacking wider application of [synthetic lethal](#) prediction methodology. This approach may not be feasible or applicable in [cancer genes](#) with a lower [mutation](#) rate than p53.

Tiong *et al.* (2014) also investigated [gene expression](#) as a predictor of [synthetic lethal](#) pairs with colorectal cancer [microarrays](#) from a Han Chinese population with a sample size of 70 tumours and 12 normal tissue samples. Simultaneously differential [expressed](#) “tumour dependent” gene pairs (which includes co-expression) between cancer and normal tissue were used to rank 663 candidate [synthetic lethal](#) interactions identified in cell line [siRNA](#) experiments. Of the top 20 gene pairs, 17 were tested for differential [expression](#) at the protein level with immunohistochemistry staining and correlation with clinical characteristics, with 11 pairs exhibiting synergistic effects. Some of the predicted [synthetic lethal](#) pairs were consistent with the literature (including *TP53* with *S6K1* and partners of *KRAS*, *PTEN*, *BRCA1*, and *BRCA2*) and two novel [synthetic lethal](#) interactions (*TP53* with *CSNK1E* and *CTNNB1*) were validated in

pre-clinical models. This serves as a valuable proof-of-concept for integration of *in silico* approaches to [synthetic lethal](#) discovery in cancer, demonstrating its utility to triage and identify [synthetic lethal](#) partners of p53 applicable to colorectal tissues. Although the experimental work was the focus of the paper, these findings show that [bioinformatics synthetic lethal](#) candidates can be validated in patient tissue samples to find those applicable to colorectal cancers (including in a non-Caucasian population).

1.2.7.5 Data Mining and Machine Learning

Recognising the utility of [synthetic lethality](#) to drug inhibition and specificity of anti-cancer [treatments](#), Jerby-Arnon *et al.* (2014) also saw the need for effective prediction of gene essentiality and [synthetic lethality](#) to augment experimental studies of SL. They developed the “Data mIning SYnthetic lethal identification pipeline” (DAISY), a data-driven approach for [genomes-wide](#) analysis of [synthetic lethality](#) in public cancer [genomics](#) data from TCGA and CCLE (Barretina *et al.*, 2012). DAISY is intended to predict the candidate [synthetic lethal](#) partners of a query gene such as genes recurrently mutated in cancer.

Jerby-Arnon *et al.* (2014) combined a computational approach to triage candidates with a conventional [RNAi](#) screen to validate [synthetic lethal](#) partners. They screened a selection of computationally predicted candidates and randomly selected genes with [RNAi](#) against *VHL* loss of function [mutation](#) in RCC4 renal cell lines. The computational method had a high [AUROC](#) of 0.779 and predictions were enriched 4-fold for validated [RNAi](#) hits over randomly selected genes. This approach detected known [synthetic lethal](#) pairs such as *BRCA1* or *BRCA2* genes with *PARP1*, and *MSH2* with *DHFR*. The [synthetic lethal](#) candidates identified with both [RNAi](#) screening and computational prediction formed an extensive network of 2077 genes with 2816 [synthetic lethal](#) interactions, and a similar network of 3158 genes with 3635 [synthetic dosage lethal](#) interactions (for [synthetic lethality](#) with over-expression). Each network was [scale-free](#), as expected of a biological network, and was enriched for known [cancer genes](#) and for [essential](#) genes in mice which could be harnessed for predicting prognosis and drug response.

The DAISY methodology (Jerby-Arnon *et al.*, 2014) compares the results of analysis of several data types to predict [synthetic lethality](#), namely: [DNA](#) copy number and [somatic mutation](#) for TCGA patient samples and CCLE cell lines. The cell lines were also analysed with [gene expression](#) and gene essentiality ([shRNA](#) screening) profiles. Genes were classed as inactivated by copy number deletion, [somatic](#) loss of function [mutation](#), or low [expression](#) and tested for [synthetic lethal](#) gene partners which are

either [essential](#) in screens or not deleted with copy number variants. Co-expression is also used for [synthetic lethality](#) prediction based on studies in yeast ([Costanzo *et al.*, 2010](#); [Kelley and Ideker, 2005](#)). Copy number, [gene expression](#), and essentiality analyses were stringently compared by adjusting each for multiple tests with Bonferroni correction and only taking candidates identified in all analyses. The predictions performed well and an [RNAi](#) screen, for the example of *VHL* in renal cancer, validated predicted [synthetic lethal](#) partners of *VHL* demonstrating the feasibility of combining approaches to [synthetic lethal](#) discovery in cancer and using computational predictions to enable more efficient high-throughput screening. While [DAISY](#) performed well statistically, co-expression and [shRNA](#) functional examination contributed less to this than the [mutation](#) and copy number analysis ([AUROC 0.683](#) alone). However, this methodology was very stringent, missing potentially valuable [synthetic lethal](#) candidates. Additionally, the software for the procedure has not been publicly released for replication.

Although the [DAISY](#) procedure performed well and has been well received by the scientific community ([Crunkhorn, 2014](#); [Lokody, 2014](#); [Ryan *et al.*, 2014](#)), showing a need for such methodology, there has not yet been widespread adoption of this approach. Co-expression analysis may exclude some [synthetic lethal](#) interactions, where inverse correlation could occur ([Lu *et al.*, 2015](#)). In the interests of a large sample size, tissue types were not tested separately despite tissue-specific [synthetic lethality](#) being likely since gene function (and by extension [expression](#), isoforms, and clinical characteristics) in cancers may often be tissue-dependent. Some data forms and analyses used, such as gene essentiality, may not be available for all cancers, genes, or tissues, and may not be reproduced.

[Lu *et al.* \(2015\)](#) propose an alternative computational prediction of [synthetic lethality](#) based on machine learning methods and a “cancer genome evolution” hypothesis. Using [DNA](#) copy number and [gene expression](#) data from [TCGA](#) patient samples, a cancer [genomes](#) evolution model assumes that [synthetic lethal](#) gene pairs behave in two distinct ways in response to an inactive [synthetic lethal](#) partner gene, either a “compensation” pattern where the other [synthetic lethal](#) partner is overactive or a “co-loss underrepresentation” pattern where the other [synthetic lethal](#) partner is less likely to be lost, since loss of both genes would cause death of the cancer cell. During the [genomes](#) evolution of cancers, the cell becomes addicted to the remaining [synthetic lethal](#) partner due to induced gene essentiality. These patterns would explain why [DAISY](#) detects only a small number of [synthetic lethal](#) pairs, compared to the

large number expected based on model organism studies (Boone *et al.*, 2007), and the disparity between screening and computationally predicted [synthetic lethal](#) candidates due to testing different classes of [synthetic lethal](#) gene pairs.

Lu *et al.* (2015) compared a [genomes](#)-wide computational model of [genomes](#) evolution and [gene expression](#) patterns to the experimental data (Laufer *et al.*, 2013; Vizeacoumar *et al.*, 2013). This more simple model performed well, with an AUROC of 0.751 (lower than DAISY), and did not rely on data from cell lines which may not represent patient disease. Lu *et al.* (2015) predicted 591,000 human [synthetic lethal](#) partners with a probability score threshold of 0.81, giving a precision of 67% and 14-fold enrichment of [synthetic lethal](#) true positives compared to randomly selected gene pairs. Discovery of such a vast number of cancer-relevant [synthetic lethal](#) interactions in humans would not be feasible experimentally and is a valuable resource for research and clinical applications. These predictions are not limited by assuming co-expression of [synthetic lethal](#) partners or evolutionary conservation with model organisms enabling wider [synthetic lethal](#) discovery. However, there remains a lack of basis for an expectation of how many [synthetic lethal](#) partners a particular gene will have, how many pairs there are in the human [genomes](#), and whether [pathways](#) or correlation structure would influence predicted [synthetic lethal](#) partners.

Large scale, computational approaches have yet to determine whether [synthetic lethal](#) interactions are tissue-specific, since Lu *et al.* (2015) used [pan cancer](#) data for 14136 patients with 31 cancer types. Experimental data used for comparison was a small training dataset specific to colorectal cancer, and based on screens for other phenotypes, which may limit performance of the model or application to other cancers. Proposed expansion of the computational approach to [mutation](#), [microRNA](#), or epigenetic modulation of gene function and tumour micro-environment or heterogeneity suggests that [synthetic lethal](#) discovery could be widely applied to the current challenges in cancer [genomics](#). This approach was also based on machine learning methodology and was not supported by a software release for the community to develop, contribute to, or reproduce beyond the gene pairs given in the supplementary results.

1.2.7.6 Mutual Exclusivity and Bimodality

Wappett *et al.* (2016) demonstrated a multi-omic approach to identify [synthetic lethality](#) in cancer with a strategy to detect bimodal patterns in [molecular profiles](#). They released this solution as the BiSEp R package (Wappett, 2014) which aims to detect subtle bimodal and non-normal patterns in [expression](#) data. Since loss of gene function is not consistently genetic. Wappett *et al.* (2016) advocate the use of [gene expression](#)

(loss of mRNA) and deletion (loss of copy number) data in addition to mutation. The BiSEp procedure was demonstrated on an analysis of 881 cell lines from CCLE (Barretina *et al.*, 2012), 442 cell lines from COSMIC (Forbes *et al.*, 2015), and RNA-Seq by Expectation Maximization (RSEM) normalised RNA-Seq data for 178 TCGA lung patient samples (Collisson *et al.*, 2014). BiSEp was demonstrated to have significant enrichment of validated tumour suppressor, synthetic lethal gene pairs (detecting 76 experimentally supported gene pairs) and was improved (detecting 420) with expression data, rather than relying on detecting loss of gene function by mutation or deletion. Wappett *et al.* (2016) identified interactions with genes relevant to cancer with support in experimental screens including *ERCC4* with *XRCC1*, *BRCA1* with *PARP3*, and *SMARCA1* with *SMARCA4*.

Wappett *et al.* (2016) demonstrated that analysis of genomics data, particularly expression data, is relevant to augment the identification of synthetic lethal interactions with screening experiments. They further showed that this is applicable in both genetically homogeneous cell lines and heterogeneous cell population from patient samples. These approach are limited however, to genes that exhibit bimodal expression patterns which do not commonly occur, particularly in normalised gene expression data. Other approaches may need to be considered for gene such as *CDH1* which were not identified by BiSEp.

Srihari *et al.* (2015) used a computational analysis to identify synthetic lethal candidate genes from mutually exclusive alterations in cancers. This analysis focused on synthetic lethality with “DNA damage response genes” in cancers, including *CDH1*, using TCGA expression and copy number data across several cancers. The 718 genes that were identified as frequently altered in cancer were enriched among essential genes in cell lines deficient in DNA damage response genes which demonstrates “induced essentiality” in a cancer model. These were tested by underMutExSL, a hypergeometric test, for synthetic lethality. Of the DNA damage response genes examined, *CDH1* exhibited the most mutually exclusive alterations with other frequently altered genes in breast cancers, including related genes in focal adhesion such as *PTK2*. These results indicate that *CDH1* may be particularly subject to “non-oncogene addiction” in breast cancers and that computational analysis is valuable to rationally identify these putative synthetic lethal genes. These results were limited to frequently altered genes in cancer and could be improved with an approach that expands to consider synthetic lethal genes that are not themselves altered in cancers or further investigation into synthetic lethal pathways.

1.2.7.7 Rationale for Further Development

Many of the approaches discussed here aimed to identify the strongest [synthetic lethal](#) pairs across the yeast or human [genomes](#) ([Deshpande et al., 2013](#); [Lu et al., 2015](#); [Wappett et al., 2016](#); [Wu et al., 2014](#)), which may not be an ideal strategy to identify interactions in particular functions or relevance to particular cancers. These demonstrate a need for computational approaches to prioritise candidate gene pairs for validation but this thesis will focus on the interactions with *CDH1* with importance in breast and stomach cancers, although these partners may be applicable in other cancers. As such, this thesis presents a query-based method, amenable to identification of candidate partners for a selected gene of functional or translational importance such as *CDH1*.

1.3 E-cadherin as a Synthetic Lethal Target

[E-cadherin](#) is a transmembrane protein (encoded by *CDH1*) with several characterised functions in the cytoskeleton and cell-to-cell signalling. Here we outline the characterised functions of [E-cadherin](#) and its importance in cancer biology. *CDH1* is a [tumour suppressor](#) gene, with loss of function occurring in both [familial](#) ([germline mutation mutations](#)) and [sporadic](#) ([somatic mutations](#)) cancers. As such, *CDH1* inactivation is a prime example of a genetic event that could be targeted by [synthetic lethality](#) for anti-cancer [treatments](#). Most notably this includes patients at risk of developing [hereditary](#) breast and stomach cancers for which conventional surgical or cytotoxic [chemotherapy](#) is not ideal and who have a known genetic aberration in their [familial](#) syndromic cancers. Effective [treatments](#) against *CDH1* inactivation would also benefit patients with [sporadic](#) diffuse gastric cancers since they often present with symptoms at a late stage.

1.3.1 The *CDH1* gene and its Biological Functions

The [tumour suppressor](#) gene *CDH1* is implicated in [hereditary](#) and [sporadic](#) lobular breast cancers ([Berx et al., 1996](#); [Berx and van Roy, 2009](#); [De Leeuw et al., 1997](#); [Masciari et al., 2007](#); [Semb and Christofori, 1998](#); [Vos et al., 1997](#)). The *CDH1* gene encodes the [E-cadherin](#) protein and is normally expressed in epithelial tissues, where it has also been identified as an invasion suppressor and loss of *CDH1* function has been implicated in breast cancer progression and metastasis ([Becker et al., 1994](#); [Berx et al., 1995](#); [Christofori and Semb, 1999](#)).

1.3.1.1 Cytoskeleton

The primary function of *CDH1* is cell-cell adhesion forming the adherens junction, maintaining the cytoskeleton and mediating molecular signals between cells. The function of the adherens complex is particularly important for cell structure and regulation because it interacts with cytoskeletal actins and microtubules. The cytoskeletal role of [E-cadherin](#) maintains healthy cellular viability and growth in epithelial tissues including cellular polarity ([Jeanes *et al.*, 2008](#)). [E-cadherin](#) is not essential to cellular viability but loss in epithelial cells does lead to defects in cytoskeletal structure and proliferation. In addition to a central role in the adherens complex, [E-cadherin](#) is involved in many other cellular functions and thus *CDH1* is regarded as a highly pleiotropic gene ([Kroepil *et al.*, 2012](#)).

1.3.1.2 Extracellular and Tumour Micro-environment

As a transmembrane signalling protein [E-cadherin](#) also interacts with the extracellular environment and other cells, most notably forming tight junctions between cells ([Chen *et al.*, 2014](#); [Tunggal *et al.*, 2005](#)). These junctions serve to both regulate movement of ion signals between cells and separate membrane proteins on the apical and basal surfaces of a cell, maintaining cell polarity. Thus [E-cadherin](#) is an important regulator of epithelial tissues by intercellular communication ([Jeanes *et al.*, 2008](#)). It also has important roles in the extracellular matrix, including fibrin clot formation. The role of intercellular interactions and the tissue micro-environment are important themes in cancer research, being a potential mechanism for cancer progression and malignancy in addition to its potential for specifically targeting tumour cells.

1.3.1.3 Cell-Cell Adhesion and Signalling

The signals mediated by tight junctions are also passed on to intracellular signalling pathways and thus [E-cadherin](#) also has a role in maintaining cellular function and growth. One such example is the regulation of β -catenin which interacts with both the actin cytoskeleton and acts as a transcription factor via the [Wingless-related integration site \(WNT\)](#) pathway ([Jeanes *et al.*, 2008](#)). Similarly, the Hippo and [phosphoinositide 3-kinase \(PI3K\)/AKT](#) pathways are implicated in being mediated by [E-cadherin](#) ([De Santis *et al.*, 2009](#); [Kim *et al.*, 2011](#)), having roles in promoting cell survival, proliferation, and repressing apoptosis. [E-cadherin](#) shares several downstream pathways with signalling pathways such as integrins and thus indirectly interacts with them, particularly since feedback loops may occur in such pathways. Conversely, the multifaceted roles of [E-cadherin](#) have been shown with over-expression in ovarian cells

promoting tumour growth, while it maintains healthy cellular functions in other cells (Brouxhon *et al.*, 2014; Dong *et al.*, 2012).

1.3.2 *CDH1* as a Tumour (and Invasion) Suppressor

E-cadherin has key roles in maintaining cellular structure and regulating growth, consistent with *CDH1* being a tumour suppressor gene. Loss of *CDH1* in epithelial tissues leads to disrupted cell polarity, differentiation, and migration (Chen *et al.*, 2014). E-cadherin loss has been identified as a recurrent driver tumour suppressor mutation in sporadic cancers of many tissues including breast, stomach, lung, colon, and pancreas tissue (TCGA, 2017).

1.3.2.1 Breast Cancers and Invasion

E-cadherin loss in breast cancers has been shown to cause increased proliferation, lymph node invasion, and metastasis with poor cell-cell contact Berx and van Roy (2009). Thus the *CDH1* gene has also been implicated as an invasion suppressor, with a key role in the epithelial-mesenchymal transition (EMT), an established mechanism of cancer progression (Hanahan and Weinberg, 2011). The epithelial-mesenchymal transition is important during development and wound healing but such changes in cellular differentiation also occur in cancers. If *CDH1* is inactivated by mutation or DNA methylation (Berx *et al.*, 1996; Guilford, 1999; Machado *et al.*, 2001), it is likely that EMT will drive growth of E-cadherin deficient cancers (Berx and van Roy, 2009; Graziano *et al.*, 2003; Polyak and Weinberg, 2009). While loss of E-cadherin is not sufficient to cause EMT or tumourigenesis, it is an important step in this mechanism of tumour progression and a potential therapeutic intervention may therefore also impede cancer progression and have activity against advanced stage cancers.

1.3.3 Hereditary Diffuse Gastric (and Lobular Breast) Cancer

CDH1 loss of function mutations also causes familial cancers, including diffuse gastric cancer and lobular breast cancer (Graziano *et al.*, 2003; Guilford *et al.*, 2010, 1999; Oliveira *et al.*, 2009). Individuals carrying a null mutation in *CDH1* have a syndromic predisposition to early-onset of these cancers, including hereditary diffuse gastric cancer (HDGC) (Guilford *et al.*, 1998). Due to carrying a dysfunctional allele, these individuals are prone to carcinogenic lesions in the breast or stomach if the remaining functional allele is inactivated, occurring more frequently and at an earlier age than in individuals with two functional *CDH1* allele. The loss of the second allele is most often through hypermethylation suppressing expression rather than mutation (Grady

et al., 2000; Graziano *et al.*, 2003; Machado *et al.*, 2001; Oliveira *et al.*, 2009), although loss of heterozygosity may also occur (Guilford *et al.*, 2010). Therefore HDGC is an autosomal dominant cancer syndrome with incomplete penetrance. The “lifetime” (until age 80 years) risk for mutation carriers of diffuse gastric cancer is 70% in males and 56% in females (Hansford *et al.*, 2015; van der Post *et al.*, 2015). In addition, the lifetime risk of lobular breast cancer is 42% in female mutation carriers (Hansford *et al.*, 2015).

HDGC affects less than one in a million people globally (Ferlay *et al.*, 2015) and represents less than 1% of gastric cancers. However, HDGC is a serious health issue for several hundred families globally. E-cadherin mutations in the germline mutation are implicated in 1-3% of gastric cancers presenting with a family history, varying between high and low incidence populations. E-cadherin is also mutated in 13% of sporadic gastric cancers.

While diagnostic testing for *CDH1* genotype has enabled more effective management of HDGC and improved patient outcomes, there are still limited options for clinical interventions (Guilford *et al.*, 2010). Individuals with a family history of HDGC are recommended to be tested for *CDH1* mutations in late adolescence and are offered prophylactic stomach surgery before the risk of developing cancers increases with age. Another option is annual endoscopic screening to diagnose early stage stomach cancers with surgical intervention once they are detected (Oliveira *et al.*, 2013). However, these early stage cancers are difficult to detect and may be missed in regular screening. Thus patients carrying *CDH1* mutations either have surgical interventions with a significant impact on quality of life and risk of complications or remain at risk of developing advanced stage stomach cancers. Due to the lower mortality rate from stomach cancers, there are increasing concerns among these HDGC families about the elevated risk of lobular breast cancers for women later in life.

The current clinical management of HDGC still has significant risks for patients and therefore a greater understanding of the molecular and cellular function of *CDH1* is important for its role in these cancers. Such studies may lead to alternative treatment strategies such as pharmacological treatments with specificity against *CDH1* null cells, once they lose the second allele. While a loss of gene function is difficult to target directly, designing a treatment with specificity against *CDH1* may also have activity in sporadic cancers in a range of epithelial cancers. Thus an effective treatment against *CDH1* mutant cancers would potentially have significant therapeutic and preventative applications in a large number of patients.

1.3.4 Cell Line Models of *CDH1* Null Mutations

Previous work published by members of our research group used a model of homozygous *CDH1*^{-/-} null mutation in non-malignant MCF10A breast cells to show that loss of *CDH1* alone was not sufficient to induce EMT with compensatory changes in the expression of other cell adhesion genes (Chen *et al.*, 2014). However, *CDH1* deficient cells did manifest changes in morphology, migration, and weaker cell adhesion (Chen *et al.*, 2014).

This *CDH1*^{-/-} MCF10A model has been used in a genomes-wide screen of 18,120 genes using siRNA and a complementary drug screen using 4057 compounds to identify synthetic lethal partners to E-cadherin (Telford *et al.*, 2015). One of the strongest candidate pathways identified by Telford *et al.* (2015) were the G protein coupled receptor (GPCR) signalling cascades, which were highly enriched by Gene Ontology (GO) analysis of the candidate synthetic lethal partners the primary siRNA screen. This was supported by validation with Pertussis toxin, known to target G_{αi} signalling (Clark, 2004), as were various candidate cytoskeletal pathways by inhibition of Janus kinase (JAK) and aurora kinase. The drug screen also produced candidates in histone deacetylase (HDAC) and PI3K which were supported by validation and time course experiments.

1.4 Summary and Research Direction of Thesis

Genomic technologies and the data available from them have immense potential for understanding of genetics and improving healthcare, including identification of genes altered in cancer for molecular diagnosis, prognostic biomarkers, and therapeutic targets. This has been demonstrated with the identification of driver genes in many cancers, distinguishing tumour subtypes by expression profiles, and the development of targeted therapies against oncogenes (such as *BRAF*) and tumour suppressors (such as *BRCA1*). Synthetic lethality is an important genetic interaction to study fundamental cellular functions and exploit them for biomarker identification and cancer treatment. They present a means to target loss of function mutations and genetic dysregulation in tumour suppressor genes by identifying interacting partners with redundant or compensating molecular functions.

CDH1 (encoding E-cadherin) is an example of a tumour suppressor gene implicated in sporadic breast and stomach cancers. Germline mutations in *CDH1* are also found in many patients with familial early onset cancers (HDGC). Discovery of synthetic lethal partners would contribute to an understanding of the molecular mechanisms driving

the growth of *CDH1* deficient **tumours** and identification of potential therapeutic targets or **chemopreventative** agents for management of **HDGC**. The clinical potential of the **synthetic lethal** approach has been demonstrated with the application of olaparib against *BRCA1* and *BRCA2* **mutations** (Lord *et al.*, 2015) but there remains the need to systematically identify **synthetic lethal** partner genes for other **tumour suppressors** such as *CDH1*. A **synthetic lethal** screen has been conducted on breast cell lines (Telford *et al.*, 2015) but these candidate **synthetic lethal** partners of *CDH1* may be further supported by the application of computational approaches to **synthetic lethal** genes and **pathways**.

While there are a wide range of experimental and computational approaches to **synthetic lethal** discovery, many are limited to particular applications, prone to false positives, inconsistent across independent approaches, or enriched for particular genes of interest. Therefore **synthetic lethal** interactions are difficult to replicate or apply in the clinic. Computational approaches to **synthetic lethality** are not widely adopted by the cancer research community and experimental approaches cannot be combined to study **synthetic lethality** at a **genomes**-wide scale. However, these show interest in **synthetic lethal** discovery in the community and the need for robust predictions of **synthetic lethal** interactions in cancer and human tissues.

Effective screening, prediction, and analysis of **synthetic lethal** interactions are a crucial part of developing next generation anti-cancer strategies. Therefore, we propose developing a computational statistical procedure to identify **synthetic lethal** interactions and construct gene networks. This will enable the development of personalised medicine targeted to particular molecular aberrations. Genetic tests and **genomic** have the potential to revolutionise cancer screening, diagnosis, and prognostics; **targeted therapeutic**, similarly, have applications in prevention and therapy of **sporadic** or **hereditary** cancers with known molecular properties.

To address the concerns raised by recent computational approaches to **synthetic lethal** discovery in cancer (Jerby-Arnon *et al.*, 2014; Lu *et al.*, 2015; Wappett *et al.*, 2016), I present similar analysis using solely **gene expression** data which is widely available for a large number of samples in many different cancers. This uses a statistical methodology the **SLIPT** developed for this purpose. To further determine the limitations and implications of **synthetic lethal** predictions, modelling and simulation was performed upon the statistical behaviour of **synthetic lethal** gene pairs in **genomics** data. Comparison of **synthetic lethal** gene candidates from public data analysis and experimental candidates, pathway analysis, and networks structure will also be pre-

sented to investigate the relationships between [synthetic lethal](#) candidates. Release of the R code used for simulation, prediction, and analysis will enable adoption of the methodology in the cancer research community and comparison to existing methods. Therefore this thesis aims to develop predictions for [synthetic lethal](#) partner genes with a focus on the example of [E-cadherin](#) to compare to the findings of [Telford *et al.* \(2015\)](#), develop of network approaches for [pathway](#) structure, and simulate [gene expression](#) on [pathway](#) structure with the [bioinformatics](#) and [computational biology](#) investigations.

1.4.1 Thesis Aims

Understanding [synthetic lethality](#) is important in cancers, having shown an impact clinical practice and patient outcomes for certain genes already. Thus this thesis aims to identify [synthetic lethal](#) gene pairs using public [gene expression](#) data. Accordingly, Chapter 3 describes the methods developed to do so, including a [synthetic lethal](#) detection methodology ([SLIPT](#)) and the release of R software packages. This chapter also serves to document the original simulation and network analysis procedures developed to support the use of [SLIPT](#) and perform analyses throughout this thesis.

This thesis also aims to demonstrate the [SLIPT](#) methodology for analysis of [RNA-Seq gene expression](#) data. Chapter 4 does so by performing an analysis to identify candidate [synthetic lethal](#) gene partners of *CDH1* in public breast and stomach cancer data ([Bass *et al.*, 2014](#); [Koboldt *et al.*, 2012](#)). Chapter 4 demonstrates the biological relevance of these candidate [synthetic lethal](#) partners by identifying [synthetic lethal](#) pathways and comparing them with the results of an experimental [siRNA](#) screen ([Telford *et al.*, 2015](#)).

Pathway analysis was extended to include [graph](#) structures in Chapter 5, which aimed to assess the importance of [synthetic lethal](#) genes within [pathway](#) structures. Chapter 5 also uses [pathway](#) structure to identify directional relationships between [SLIPT](#) and [siRNA synthetic lethal](#) candidates and explore the disparity between them. The [SLIPT](#) methodology is supported by simulation-based investigations in Chapters 3 and 6, which evaluate the ability of [SLIPT](#) to detect known [synthetic lethal](#) genes in simulated data. Graph structures were also used in Chapter 6 to determine the effect of [pathway](#) structures of [synthetic lethal](#) detection with [SLIPT](#) in simulated data and ascertain that the simulation results were comparable to [expression](#) data containing complex correlation structures within biological pathways.
